1. Welcome to COPA-DATA help

GENERAL HELP
If you cannot find any information you require in this help chapter or can think of anything that you would like added, please send an email to documentation@copadata.com (mailto:documentation@copadata.com).

PROJECT SUPPORT
You can receive support for any real project you may have from our Support Team, who you can contact via email at support@copadata.com (mailto:support@copadata.com).

LICENSES AND MODULES
If you find that you need other modules or licenses, our staff will be happy to help you. Email sales@copadata.com (mailto:sales@copadata.com).

2. Network
zenon networks can be set up very quickly and securely.
zenon in the network allows you, among other things:

- Complete access to different computers, actions such as acknowledgment of alarms to a workspace are therefore visible to all others
- Centralized logging and archiving
- Creation of redundant systems (see redundancy (on page 72), circular redundancy (on page 82))
- Integrated evaluation methods for redundancy switching
- Creation of distributed systems (see multi-project administration (on page 25))
- Use of zenon Web Server and zenon Web Client for mobile access
- Use of zenon in a terminal server environment (on page 56)
- Use of strong encryption (on page 42)
- Concurrent work on a project of several stations (see distributed engineering)

License information

Part of the standard license of the Editor and Runtime.

SIMPLE ADMINISTRATION OF THE ZENON NETWORK

The well-thought-out network functionality of zenon makes it possible to implement projects as distributed on different computers and to create complex network constellations (on page 17) very efficiently. In doing so, project constellations can also be thought out in such a way that certain project content is only visible at a certain location (a certain computer) for an activity. The zenon Editor supports users in creating and configuring such constellations.

The integrated topology administration (on page 62) creates interrelationships for the individual projects in the process, with the attendant computers in graphical form. A testing routine checks the configured structure to see that it is complete and that there are no configuration errors.

Information

Note for network projects, the roles (on page 8) (Primary Server, Standby Server, Client) in which modules and functions (on page 99) can be administered and executed.

WAN

Within a network, zenon transfers data spontaneously – and is thus already optimized for use with in a WAN. Depending on the configuration, it is also recommended that the watchdog traffic (on page 16) between the client and Primary Server is limited. The communication distance between client and Primary Server can be automatically closed. The routers then establish a new connection when data exchange is absolutely necessary.
**ZENON WEB SERVER**

The zenon Web Server allows access to Runtime via the intranet or internet. No adaptations to the project are necessary. Access is via the zenon Web Client. This offers the same look & feel as zenon Runtime. The zenon Web Server is available as:

- **zenon Web Server**: Pure monitoring functionality.
- **zenon Web Server Pro**: Complete operation and monitoring functionality. It is possible to directly engage in processes over the web.
- **zenon Web Server Pro Light**: Limited functionality of zenon Web Server PRO for use with zenon Operator.

3. **Concepts**

With zenon, it is possible to create various network topologies, starting from a simple client-server model through to comprehensive multi-hierarchical models.

IT-specific terms such as Server and Client are also used in zenon. However, in order to achieve unique identification of the individual components for complex multi-hierarchical structures with various computers and projects involved, we always speak of roles in zenon. Roles are always to be considered from the point of view of a project.

zenon Runtime can start one or more projects depending on the project setup (see also multi-project administration (on page 25)). In doing so, the computer on which Runtime is started assumes one of the following roles for the respective projects:

- Primary Server
- Standby Server
- Client

These roles are shown below using examples in different topologies.

💡 **Info**

If, in the course of this documentation, we speak of Primary Server, Standby Server or Client, the role that the computer takes for the project is always meant.
3.1 Client-server model

In the Client-Server model, one computer is the Primary Server; all other computers are Clients.

- Computer 1 is the Primary Server for Project A.
- Computer 2 is the Client for Project A.

For details, see the Client-Server model (on page 20) chapter.

3.2 Redundant model

In the redundant model, one computer is the Primary Server and one computer is the Standby Server. All other computers are Clients.

If the Primary Server fails, the Standby Server takes on this role. All Clients connect to the new Primary Server.

**REDUNDANCY WITHOUT CLIENTS**

- Computer 1 is the Primary Server for Project A.
- Computer 2 is the Standby Server for Project A.
- If Computer 1 fails, Computer 2 is the new Primary Server for Project A.

**REDUNDANCY WITH CLIENTS**

- Computer 1 is the Primary Server for Project A.
- Computer 2 is the Standby Server for Project A.
If Computer 1 fails, Computer 2 is the new Primary Server for Project A. All Clients automatically connect to Computer 2.

For details, see the Redundancy (on page 72) chapter.

### 3.3 Multi-hierarchical models

It is possible to create different multi-hierarchical topologies with the help of multi-project administration (on page 25). In doing so, it is possible to start several projects on one computer. The computer assumes a certain role for the project in the process.

Examples:

**MULTI-CLIENT MODEL**

- Computer 1 is the Primary Server for Project A.
- Computer 2 is the Primary Server for Project B.
- Project I runs on Computer 3 (integration project) as a standalone project and starts Projects A and B.
  - Computer 3 is a Client for both of these projects.

**MULTI-SERVER MODEL**

- Project I runs on Computer 1 (integration project) as a standalone project and starts Projects A and B.
  - Computer 1 is the Primary Server for both of these projects.
- Project I runs on Computer 2 (integration project) as a standalone project and starts Projects A and B.
  - Computer 2 is a Client for both of these projects.
- Computer 3 is the Client for Project A.
- Computer 4 is the Client for Project A.
MULTI-CLIENT-MULTI-SERVER MODEL

- Project I runs on Computer 1 (integration project) as a standalone project and starts Projects A, B, C and D.
  - Computer 1 is the Primary Server for projects A and B.
  - Computer 1 is the Client for projects C and D.
- Project I runs on Computer 2 (integration project) as a standalone project and starts Projects A, B, C and D.
  - Computer 2 is the Client for projects A and B.
  - Computer 2 is the Primary Server for projects C and D.
- Project I runs on Computer 3 (integration project) as a standalone project and starts Projects A, B, C and D.
  - Computer 3 is the Client for projects A, B, C and D.

For details, see the multi-project administration (on page 25) chapter.

4. Requirements

A basic requirement for using zenon is a functional Windows network.

GENERAL

The following requirements must be met:

- TCP/IP as the network protocol
- Functional naming, can be chosen as DNS, WINS or local HOST files.
- Free TCP Port 1100:
  If a network project is loaded, zenon Runtime automatically starts the zenNetSrv network service. This program opens port 1100. This must therefore be reachable remotely and may not be blocked by a firewall.

Info
zenon networks work with all supported operating systems.
IPV4 UND IPV6

The zenon network allows the choice of using IPv4 or IPv6. Dual operation is not possible. The setting is made via:

- Network configuration in the Startup Tool
- In zenon6.ini

If this setting is changed, all ongoing zenon processes must be restarted. This concerns `zenAdminSrv`, `zenSysSrv`, `zenLogSrv` and `zenDBSrv` in particular.

The following components are not affected by the setting; they always use IPv4:

- Driver communication with the PLCs
- Protocol communication in the Process Gateway plug-ins
- Workbench and Runtime communication in straton

⚠️ Attention

IPv6 only works with zenon version 7.00 onwards. No versions prior to zenon version 7.00 can be started if this is active.

PORTS USED

For communication within zenon, only TCP ports are used; no UDP ports are used. zenon requires the following ports in a network:

<table>
<thead>
<tr>
<th>Service</th>
<th>File</th>
<th>Goal</th>
<th>TCP-port</th>
</tr>
</thead>
<tbody>
<tr>
<td>Network service</td>
<td>zenNetSrv.exe</td>
<td>Runtime communication.</td>
<td>1100</td>
</tr>
<tr>
<td>Transport service</td>
<td>zenSysSrv.exe</td>
<td>Data transfer by means of Remote Transport (Editor).</td>
<td>1101</td>
</tr>
<tr>
<td>zenon Web Server</td>
<td>zenWebSrv.exe</td>
<td>On-site logging machine between web client and Runtime</td>
<td>1102</td>
</tr>
</tbody>
</table>

CHECK THE REQUIREMENTS

NAME RESOLUTION

To check the name resolution:
1. Start the windows command line (cmd.exe)

2. Enter the following command: ping COMPUTER NAME.

3. If the name resolution is correct, you receive the IP address of the computer with Runtime as the answer; otherwise you receive an error message

**TCP PORTS**

To check the contactability of the TCP port 1100:

1. Start Runtime with a network project on a Remote computer:
   This starts the program zenNetSrv.exe and the TCP port 1100 is opened

2. Start the windows command line (cmd.exe)

3. Enter the following command: telnet COMPUTERNAME 1100.

4. As soon as a connection is established, the content of the command line window disappears; otherwise there is an error message.

**Note:** From Windows Vista onwards, the Telnet command is no longer part of the operating system and must be installed separately. You can find instructions for this in the operating system help pages (search for: Telnet).

### 4.1 Time synchronization in the network

With network projects, all computers in the network must be time-synchronized. zenon automatically carries out the synchronization necessary for this.

In a topology with several Primary Servers (such as circular redundancy (on page 82)), it is recommended that time synchronization is implemented by means of an external time service (such as DCF77) or Windows resources. In this case, the automatic time synchronization in zenon must be deactivated.

⚠️ **Attention**

*If the time difference between the server and the client is more than 5 seconds, no more files are synchronized.*
DEACTIVATING TIME SYNCHRONIZATION IN ZENON

If the time synchronization is to be turned on or off manually, the following entry in `zenon6.ini` must be amended:

```
[Netz]
TIMESYNCH=1 -> automatic time synchronization active (default)
TIMESYNCH=0 -> automatic time synchronization inactive
```

EXTERNAL TIME SYNCHRONIZATION USING THE OPERATING SYSTEM

If the automatic time synchronization in zenon was deactivated, synchronization can be carried out via the operating system. To do this, a time server must be specified for this (with or without an external time service such as DCF77), which takes on the time synchronization with the other computers.

In the conventional Client-Server/Standby topology (without multi-project administration), the Primary Server is the active time master. This should keep its own time itself by means of an external time service if possible. The respective clients get the current time from this (depending on the timeout that has been set) and update their own times accordingly. Communication is carried out via SNTP (Simple Network Time Protocol), which takes the delay time into account.
Watchdog

Time synchronization is carried out periodically at the set time-out time.

When using the standard setting of 30 seconds for the Network communication timeout property in the Startup Tool, the network service (zenNetSrv.exe) of each client sends a watchdog every 10 seconds during online operation to the network service (zenNetSrv.exe) of the Primary Server. If the Primary Server responds to at least one of the three watchdogs within the 30 seconds, the client assumes that the network connection is working.

Configuration in the Startup Tool:

Application -> Options -> Network configuration tab -> Option Network communication timeout.

Configuration in zenon6.ini:

Alternatively, the setting can be made directly in zenon6.ini:

[Netz]

NET_TIMEOUT_MSEC=30000

(time-out in milliseconds, default: 30000.)

Note the additional configuration necessary in WAN (on page 16).

Attention: The minimum timeout time is 5 seconds. If you define a lower value, this is interpreted as 5 seconds.

COMMANDS UNDER WINDOWS

For external synchronization using Windows, enter the following command with the respective necessary arguments in the console for command: NET TIME \[\Computer name | /DOMAIN[:Domain name] : /RTSDOMAIN[:Domain name]] [/SET] [/YES]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NET TIME</td>
<td>Synchronizes the time of the computer with that of another computer or another domain or Displays the time for a computer or a domain</td>
</tr>
</tbody>
</table>
If this command is executed without further arguments, then the current date and the current time of the computer that was defined as the time server for the domains is displayed.

<table>
<thead>
<tr>
<th><strong>Computer name</strong></th>
<th>The name of the computers that checks or is to be synchronized.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DOMAIN[:Domain name]</strong></td>
<td>The time is synchronized with the primary domain controller of the Domain name domain.</td>
</tr>
<tr>
<td><strong>RTSDOMAIN[:Domain name]</strong></td>
<td>The time of the computer is synchronized with a reliable time server from the Domain name domain.</td>
</tr>
<tr>
<td><strong>/SET</strong></td>
<td>Synchronizes the clock of the computer with the stated computer and/or the stated domain. After the command has been set, the server time is displayed and a request is made to see if this time is to be set.</td>
</tr>
<tr>
<td><strong>/YES</strong></td>
<td>Displays the current server time and synchronizes this with the local computer without a further request or confirmation.</td>
</tr>
</tbody>
</table>

**Example**

```
NET TIME  \Server /SET /YES
```

### 4.1.1 Time synchronization in the WAN

In a WAN and for dial-up connection, the standard defined value of 30 seconds for the timeout means that the connection would probably be maintained permanently.

Select a timeout time in the WAN that only initiates the establishment of a connection at the desired interval. However, note: The longer the time-out, the later server failures are detected. For example, if you select 64800 as the time for the timeout, the time-out time is 18 hours. A connection is made every 6 hours and a watchdog is sent. A server failure would thus only be noticed after around 18 hours.

**Information**

*If no entry for the timeout is defined in zenon6.ini, the standard timeout of 30 seconds is used when Runtime is started.*
FUNCTION SCREEN SWITCH

Active data is requested when a screen is switched. Procedure:

- A check is made to see if a watchdog was sent to the Primary Server in the last 30 seconds.
- If this is not the case, a watchdog is sent to the Primary Server immediately. The waiting time for a response is 40 seconds.
- If a Server break down is recognized, the zenon network service automatically tries to reconnect every 30 seconds.

This would lead to a permanent connection establishment in the WAN network. This behavior can lead to entries in \texttt{zenon6.ini} being amended:

1. Open \texttt{zenon6.ini}.
2. Navigate to the [\texttt{NETZ}] section.
3. Create or edit the entry \texttt{NET\_CONNECTWAIT\_MSEC=30000}
   This defines the value for a reconnect in milliseconds.
   Maximum value: Time-out time
4. Create or edit the entry \texttt{NET\_CONNECTCOUNT=}
   This defines the number of repetitions for a reconnect per cycle.
   The default is 0 repetitions, this means 1 attempt at reconnection.

5. Setting up the zenon network

In the zenon network, you work with:
Setting up the zenon network

### Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Server:</strong></td>
<td>Computer with connection to the PLC. The server takes on the administration of process and project data exclusively. Communication is checked by means of a watchdog (on page 13). In the event of a server failure, the Standby Server undertakes its tasks, provided a standby was defined. As soon as the server is ready again, it automatically takes on its tasks and synchronizes all data.</td>
</tr>
<tr>
<td><strong>Standby Server:</strong></td>
<td>Takes on, in redundant systems, the role of the server, if this fails. It acts like a client in the network, but also saves all data like the server. In the event of hardware redundancy, the standby communicates with the redundant PLC both ways. The standby works with an internal buffer. Data loss during the downtime between server failure and the standby taking on the server role is thus avoided.</td>
</tr>
<tr>
<td><strong>Clients:</strong></td>
<td>Each computer on which Runtime is started is a client. Clients connect to the server to receive process data or to send this.</td>
</tr>
<tr>
<td><strong>Data server:</strong></td>
<td>The Data server is a computer with direct communication to the process but no server tasks. In normal operation, the data server sends all data to the Server, which manages data storage and data distribution. In the event of a network or server breakdown, the data server continues to work as a single station and therefore guarantees proper operation of the process. The data is transferred as soon as the server connection is re-established. <strong>Field of application:</strong> An on-site operating system without powerful hardware, such as an IPC or CE terminal. Complete data archiving and data distribution is carried out by the data server. On-site operation is still possible in the event of a server failure. This is not the case in a conventional Client-Server model.</td>
</tr>
</tbody>
</table>

---

**Information**

*Server and client are not defined in relation to a computer, but in relation to a project.*

*If the names of the Server or Standby Server are changed, these cannot be reloaded. They are only updated by restarting Runtime.*

---

**TOPOLOGIES**

zenon supports several network topologies:

- Client server network (on page 20): The same project runs on the server and all clients.
- Multi-server network: A client can access different servers and thus display the data of different projects at the same time.
- Multi-client-multi-server model: All clients and servers communicate with each other. Other projects can be accessed from each project.

**CONFIGURING THE NETWORK**

To make a network network-compatible:

1. navigate to the Network node in properties
2. Activate the Network active property
3. Use the Server 1 property to define the computer that takes on the server role in the project

**Note:** The IP address is not sufficient; the name of the computer must be entered.

If necessary, you still configure the following in this section:

- Standby Server (on page 75): Server 2 property:
- Redundancy (on page 72): Redundancy type property:
- Termination message: Defines if, when Runtime is ended on a server, the clients are informed 70 seconds in advance

With this, you have configured the basic properties. Repeat these steps for all clients in the zenon network. Remote computers can also be set up using remote transport.

⚠️ **Attention**

*Name issue for Server 1 and Server 2:*

- The computer name must be entered. The IP address is not permitted.
- "localhost" must not be used.
5.1 Client-server model

In the conventional Client-Server model, only one project is used, which is started on all computers involved. In doing so, a certain computer is the Primary Server for this project. All other connected computers are Clients.

To set up the Client-Server model, the following must be the case in the project:

- The **Network active property** must be activated
- The name of the computer that is to be the Primary Server is to be entered in the **Server 1 property**

**Recommendation:** Select the most powerful computer in the network as the Primary Server.

In the zenon Client-Server model:

- Only the Primary Server has a direct connection to the PLC
- The Primary Server administers all process data (such as online data, archive data, alarms, recipes, etc.)
- The Primary Server administers all project data (such as screens, functions, defined variables, etc.)
- Each other computer starts as a Client in the network
- Each client establishes the connection to the Primary Server when Runtime is started,
  - synchronizes the project data and
  - displays the current process data
5.1.1 Configuring the Primary Server

The Primary Server makes the connection to the PLC and administers all data, both online data and configuration data. The Clients synchronize their data with the Primary Server.

To set up the Primary Server

1. **Activate the Network active property**

2. Define the computer that is to be the Primary Server for the project using the **Server 1** property.
   
   **Note:** The IP address must not be used; the name of the computer must be entered.

3. Note the correct configuration of the internal variable drivers (on page 113)

4. Create **AUTOSTART** and **AUTOEND** scripts (on page 113) for the clients if necessary

**Attention**

*Name issue for Server 1 and Server 2:*

- The computer name must be entered.
  
  The IP address is not permitted.

- "localhost" must not be used.

*If the development computer on which you created the project is also the Primary Server, configuration is now complete.*
5.1.2 Configuring the clients

Clients can be set up via Remote Transport, via the network topology or manually. Setup via Remote Transport or the network topology is recommended.

For this, the following applies:

- If the development station also is a client, simply start the Runtime there.
- You set up all other clients either via Remote Transport (on page 22), network topology (on page 62) or manually (on page 62).
- If special processes are to be executed on the clients, a respective script in the project must be created, which defines the behavior on startup (AUTOSTART_CLIENT script (on page 113)) and when being ended (AUTOEND_CLIENT script (on page 113)).

Set up client with Remote Transport

By default, Remote Transport always transports the Runtime files to the computer that is defined as the server in the network properties. To set up clients from the development computer by Remote Transport, the Remote Transport connection must be set up before the Client is set up.

To set up clients using Remote Transport:

1. Open the General node in Project Properties.
2. Click on the Remote transport property.
3. The dialog Remote Transport is opened
4. Enter, in Connection under Name, the name of the client in the network.
5. Close the project configuration with ok.
   To continue to use Remote Transport, it is best to use the toolbar symbols.
7. Transport all Runtime files to the client with Remote Transport.
8. Set the start project for the client with Remote Transport.
10. Close the Remote Transport connection
Setting up the zenon network

Setting up a Client by means of network topology

Network topology is suitable for setting up several Clients at the same time. In doing so, Runtime files can be transferred to several computers at the same time by means of multiple selection. For details, see the network topology (on page 65) chapter.

Setting up the client manually

To configure clients for the start of Runtime:

1. Close zenon Editor and zenon Runtime.
2. Open the file `zenon6.ini` with a text editor.
   You can find the file in the folder `%ProgramData%\COPA-DATA\System\`
3. Remove the line `VBF30=....` or comment this line out.
   (This entry defines which project is to be loaded when Runtime is started.)
4. Leave the Editor closed and start Runtime.
5. A request is made in a dialog, requesting which project is to be loaded.
6. Activate the check box for the Load project from Runtime server option.
7. Enter:

a) Runtime server: Computer that is set up as the Primary Server (on page 17). The name can be entered directly or selected from a list using the ... button.

b) Project name: Name of the project that runs on the Primary Server.

   Note: Ensure that the project names are correct. If the folder name does not correspond to the project name, the project name must be changed here!

c) Project target folder: Folder for Runtime on the client's local hard drive. You either can select an existing folder using the ... button or enter a path manually. If a folder that does not exist is entered, this is created automatically.

d) Confirm the input by clicking OK.

8. zenon Runtime:

   a) Creates a connection to the Primary Server
   b) Copies its Runtime files to a project target folder
   c) Starts Runtime
   d) Requests a restart of Runtime if necessary

9. The entry VBF30=... in the zenon6.ini file is set on the project target folder.

   Runtime then starts the network project automatically on the client each time it is started.

Repeat this process for each client.

Behavior in Runtime

Network projects can be operated in the same way in the network by all computers in Runtime and Clients and are visualized in the same way. If there is no valid project defined when Runtime is started, the dialog to define the Runtime projects is opened. For details, see the Set up client manually (on page 23) section.

Differences between the Primary Serve and the Client:

- Only the Primary Server of the project has a connection to the hardware and administers the process data.

- The other computers (Clients) receive, from this:
  - Current values of the variables
  - Chronological Event List system messages
  - Alarm information
• Recipes
• Archive data
• etc.

The transfer from the Primary Server to the Clients (such as a value change from a driver) is spontaneous and event-triggered (such as calling up a trend screen, which needs archive data from a Primary Server).

MONITORING THE CONNECTION

When using the standard setting of 30 seconds for the Network communication timeout property in the Startup Tool, the network service (zenNetSrv.exe) of each client sends a watchdog every 10 seconds during online operation to the network service (zenNetSrv.exe) of the Primary Server. If the Primary Server responds to at least one of the three watchdogs within the 30 seconds, the client assumes that the network connection is working.

5.2 Multi-project administration

Multi-project administration makes decentralized solutions possible. Sub-projects can be distributed to different computers. The individual computers in turn can be the Primary Server, Standby Server or Client for the respective sub-projects.

The following is possible with the help of multi-project administration:

- Several projects in one workspace can be edited in the Editor at the same time
- Several projects can be started at the same time and thus variables, functions, archives etc. from other projects can be accessed directly throughout projects

Information

Multi-project administration is not available under zenon Operator. Here, only one project and a global project per workspace can be created and administered in the Editor. Runtime can only start one project.

STRUCTURE

An integration project that is loaded in Runtime as a start project is required.
zenon creates a multi-hierarchical project tree, at the top of which is the integration project. Multi-project administration makes it possible to place the projects in a logical connection to one another.

**Information**

Configure the topology and check it with the zenon network topology (on page 62).

**WORK EFFICIENTLY WITH MULTI-PROJECT ADMINISTRATION AND THE PROJECT HIERARCHY**

zenon enables you to reuse data and screens from existing projects consistently. zenon multi-project administration makes a logical connection between the individual projects and places these in a hierarchical connection to one another. The user can display this project hierarchy graphically in the zenon Editor, by dragging the projects to the desired position with the mouse and thus creating a multi-hierarchical project tree.

The project that is highest in the hierarchy is the integration project. All other projects are subordinate to this project. The data from individual projects is available throughout all projects in the project structure.

The zenon multi-project structure is comparable to a file folder:
Additional sheets – zenon projects – can be added at any time. The folder always automatically covers all information of the sheets stored in there. It is possible to browse through the pages at any time and look at the information, without taking the individual pages out. In the zenon multi-project structure, users can change between the individual screens or projects without having to take these out.

The integration project can be compared to the contents of the file folder. It serves as a central navigation project and makes it possible to display screens or data from the subordinate projects. The individual projects are autonomous and can continue to be operated autonomously. Access from a project to the data or screens of another project is enabled via the zenon standard interfaces. Expansions or amendments to projects are made directly in the individual projects. Any maintenance work that may be carried out only has an influence on the respective project; the overall system remains unaffected by this.

**MULTI-PROJECT ADMINISTRATION MEANS**

- Small-sized, clear structures.
- Easy, quick and clear maintenance of the individual projects. It is possible, for example, to deactivate individual projects without influencing the others. In the same way projects can be distributed to different processors.
- Load distribution.
- Cross-project operation, as all projects on a processor are simultaneously activate.
- Multiple-hierarchy network structure allows the centralization of data (measured values, alarms, plant information, archive data, etc.) in a higher-ranking level.
- No limit on projects per processor.
- Summary of projects to large control rooms.
- Node structure – physical network separation.

### 5.2.1 The integration project

The integration project administers subprojects that can be accessed in Runtime. The integration project can be used as a pure administration project in multi-project administration (for example just for the navigation to the sub-projects) or also a a complete productive project (with its own PLC connection,
Setting up the zenon network

archiving, etc.). If the integration project is used as a start project, all sub-projects are automatically started in Runtime.

In an integration project, you can for example create central Alarm Message Lists or Chronological Event lists for all subordinate projects with a few mouse clicks. This allows the alarms of all subprojects in the Alarm Message List of the integration project to be displayed in chronological order.

⚠️ Attention

*When designing the multi-project administration, ensure that the navigation (on page 31) works.*

### 5.2.2 Definition of the structure in the Editor

The structure is created by simply dragging & dropping in the Editor. You also need, in addition to productive projects, an integration project that administers all other projects. Because single-user projects do not send data to other computers, a Primary Server must be defined in each (sub-)project. The integration project itself can also be a network-capable productive project.

**EXAMPLE**

Three projects are used in this example:

- Integration project **IPRO**
- Productive project **PRO1**
- Productive project **PRO2**

To create the structure:

1. Create:
   - IPRO
   - PRO1
   - PRO2
   - And define a Primary Server for each computer
     (the integration project can also be implemented as a standalone project)
2. In the Project Manager, drag PRO1 to IPRO by holding the left mouse button

3. Do the same for PRO2

4. PRO1 and PRO2 are now displayed in the Project Manager as branches of the IPRO

The hierarchical structure of the network has thus been created.

**Information**

*In order for elements of subprojects, such as screens, variables or functions to be able to be selected, the Keep project in the memory function (in the project context menu) must be activated.*

5.2.3 Transferring and starting projects

With the help of the network topology (on page 62), the integration project can automatically be transferred to the respective target computer with all subprojects. All subprojects are also automatically transferred if the integration project is also the start project.

For details of network topology, read the Administering and checking network topology (on page 62) chapter. You can find the configuration of the computer with an example for automatic transfer of sub projects in the Configuration of computers in the network (on page 68) section.
TRANSFERRING AND STARTING PROJECTS MANUALLY

Remote Transport can be used to transfer and start projects manually. Each project is individually transferred to the corresponding computer.

- With Remote Transport, move all Runtime files of PRO1 to its Primary Server.
- Set the start project with Remote Transport.
- Start the Runtime with Remote Transport.
- Stop the online connection.
- Do the same for PRO2.

**Info**

In order to transfer the integration project and both subprojects to a Client via Remote Transport, 3 Remote Transport processes are necessary (a process for each project).

Network topology (on page 62) is preferred here, because all projects can also be transferred to several computers at the same time.

5.2.4 Administering projects

You have the following possibilities, among others, for accessing the data from subprojects:

- Navigation between projects (on page 31)
- Using variables or functions from another project (on page 33)
- Sending recipes to different variables in different projects (on page 34)
- Create archives for use throughout projects (on page 35)
- Creating a joint AML or CEL for different projects (on page 38)
**Attention**

During configuration, note the roles in which the modules and functions are executed (Primary Server, Standby Server, Client). You can find a list of the possible configurations here: Behavior of modules in the network (on page 99).

---

**Navigation between projects**

When administering more than one sub-project in an integration project, it is absolutely necessary to ensure that it is possible to switch from one subproject to another or to the integration project in Runtime.

**Hint:** Create a template that is always in the foreground. Create a screen with navigation buttons based on this.

**SCREEN SWITCH TO SUBPROJECTS**

To switch between screens of individual projects, use the zenon screen switching function. In order for the navigation to be available at all times, first create a frame that is always in the foreground:

1. Create a new template that offers space for the navigation controls.
2. Assign it the Always in the foreground property.
3. Activate the properties Border type and Title (this means that the template can be moved in Runtime).
   - Of course a template can also be used without a frame and title being in a fixed position.
4. Create a screen with navigation buttons on the basis of this template

**EXAMPLE OF SWITCHING BETWEEN PRO1 AND PRO2**

1. Create a new Screen switch function.
2. If there is more than one project available in the current workspace, the dialog to select a screen for the selection of a project is expanded.

4. Select the start screen of PRO1 and close the dialog with OK.

5. Repeat the process for PRO2.

6. Add two text buttons with the text PRO1 and PRO2 to the navigation screen.

7. Link the two text buttons to the functions that have been created.

Attention

zenon does not check in the Editor to see if the network structure in Runtime actually allows access to the selected project/screen.

For example, in the Editor, screen switching to a screen in the integration project can be created in the project PRO1. This switching only works in Runtime if the integration project has also been started. This screen switching will not work on a computer on which the PRO1 project (start project) has been started.
Variables and functions

you can access variables and functions from other projects in the same workspace directly by means of **dynamic elements**.

**VARIABLE EXAMPLE**

1. Open the IPRO start screen.
2. Add a new **counter value** dynamic element.
3. The variable selection dialog now opens.

   ![Variable selection dialog](image)

4. Here, you can select not just variables from the IPRO. To select a variable from a different project:
   a) Click on a project in the left list area
   b) You are offered the attendant variables
   c) select the variable you want to assign

5. Select a variable from PRO1 or PRO2.

Proceed in the same way for functions.
Attention

zenon does not check in the Editor to see if the network structure in Runtime actually allows access to the selected project and its variables/functions.

For example, in the Editor, in project PRO1, a variable from the integration project can be selected. This connection only works in Runtime if the integration project has also been started. This connection will not work on a computer on which only project PRO1 has been started (start project).

Recipes

You can write values to variables from different projects of the workspace in a recipe.

RECIPE EXAMPLE

1. In the project IPRO open the node Recipes.
2. Create, under Standard recipe recipes a new recipe with the name Recipe 1.
3. Open the context menu of Recipe 1 and select Add variable.
4. The dialog for selecting variables is opened
5. Here, you can select not just variables from the IPRO. To select variables from other projects:
   a) Click on a project in the left list area
   b) You are offered the attendant variables.
   c) Select variables from PRO1 and PRO2.
   d) The name of the respective project is also placed in front of the variable name in variable list of the recipe.

![Variable list](image)

Proceed in the same way for the Recipegroup Manager.

⚠️ Attention

zenon does not check in the Editor to see if the network structure in Runtime actually allows access to the selected project and its variables.

For example, in the Editor, in project PRO1, a variable from the integration project can be selected. This connection only works in Runtime if the integration project has also been started. This connection will not work on a computer on which only project PRO1 has been started (start project).

---

Archives

Values of variables of different projects of the workspace can be recorded in an archive. The values recorded in this way can be filtered, displayed in list form or trend form, and they can be printed or exported just like data from normal archives.

EXAMPLE OF ARCHIVE

1. In the project IPRO open the node Historian.
2. Create a new archive named BA - BASIS.
3. Open the context menu of RECIPE1 and select Add variable.
4. The dialog for selecting variables is opened.

![Variable selection dialog](image)

5. Here, you can select not just variables from the IPRO. To select variables from other projects:
   a) Click on a project in the left list area
   b) You are offered the attendant variables
   c) select the variable you want to assign

6. Select variables from PRO1 and PRO2.
7. The project name is written in front of the variable name in the archive variable list.

Attention

*zenon does not check in the Editor to see if the network structure in Runtime actually allows access to the selected project and its variables.*

*For example, in the Editor, in project **PRO1**, a variable from the integration project can be selected. This connection only works in Runtime if the integration project has also been started. This connection will not work on a computer on which only project **PRO1** has been started (start project).*

**REDUNDANCY**

After the selection of variables has been concluded, a message box indicates that seamless recording is guaranteed under all circumstances.
The project PRO1 is executed redundantly; one computer is the Primary Server, a second computer is the Standby Server.

The same applies for the project PRO2.

The integration project with the subordinate projects PRO1 and PRO2 is started on a third computer. This is the client for all subprojects.

If variables of the projects PRO1 and PRO2 are now archived in the integration project, then the computer receives the data about the network from the respective Primary Server from PRO1 and PRO2.

If, for example, the Primary Server of PRO1 fails, for the time period until the Standby Server of PRO1 has taken over the Server role, there would be alternative values in the archive for variables from PRO1.

**Cause:** The Standby buffer of the seamless redundancy only caches local project variables and only tracks these.

**Solution:** In order to ensure recording without interruptions, the archiving must be local in a redundantly-executed subproject.

### Alarms and CEL

In zenon, system messages and alarms from different projects of a workspace can be displayed together in a list. These entries can be filtered, displayed, printed or exported just the data from normal Alarm Message Lists or Chronological Event Lists.

**AML example**

1. Create an AML screen.

2. Add control elements to the screen via Control elements → Add templates.

3. Create a function Screen switch for this screen.

4. The filter dialog for alarm lists is opened.

5. Open the Project tab.
6. Select the project that is to be displayed in the AML of the IPRO. Multiple selection button Ctrl plus a mouse click.

7. Open the Column settings tab.
8. **Select the Project name property for display in Runtime.**
You thus gain an overview of the project from which an alarm comes in Runtime.

![Image of project settings](image)

Proceed in the same way for the Chronological Event List.

5.3 **Horizontal transparency**

Multi-project administration also allows **horizontal transparency**.
Horizontal transparency means that all projects that are on the same level can be called up on one computer. The requirement for this is an integration project (on page 27) with corresponding navigation, which starts these projects.

EXAMPLE

Several terminals belong to one machine. Each has its own visualization project. With the help of horizontal transparency, it is possible to show and operate, on each terminal, its own project and all other projects. This way the entire machine can be monitored and operated from each terminal.

5.4 Optimization for projects with a large number of Clients

Large network projects can, under certain circumstances with standard settings, place the Primary Server under full load for a period of time by reloading many Clients. The extent of the load depends on several factors (Primary Server resources, available bandwidth, etc.).

Guideline values:

- Runtime files of 10 MB or larger
- More than 50 clients

In this case, the reloading process can be optimized in order to prevent all Clients being reloaded at the same time. You can make this happen with the \texttt{RELOADDELAY\_SEC} entry in \texttt{project.ini}. With this,
reloading is delayed by a random value.

For this:

1. Open `project.ini` in the `\Project_SQL_folder\FILES\zenon\system\folder` 
   **Hint:** Highlight the project in the project manager and press the keys Ctrl+Alt+E; the Windows Explorer opens the `\Project_SQL_folder\FILES\folder`

2. Navigate to the `[NET2]` section

3. Create the entry `RELOADDELAY_SEC=Value`

4. Select a value value for the delay.

   *When reloading, a random delay in seconds is calculated for each client, which is between 0 and the selected value. 0 means no delay (standard action). The selected value has no influence on standalone projects, the Primary Server or the Standby Server.*

   **Note:** This entry should only be set in every large projects with a noticeable delay when reloading. The standard settings provide better performance in normal projects.

### 6. Strong encryption of network communication

zenon enables strong encryption of communication in the zenon network. Strong encryption works from zenon Version 7.0 for all supported operating systems and for the Web Client.

If encryption is active, communication between the Primary Server, Standby Server, Clients and Web Clients is in encrypted form; the zenon Web Server only forwards data packets and is not affected by encryption.

---

**Information**

*Network communication was also encrypted in earlier versions of zenon. The method has changed with version 7. The term "encryption" in conjunction with zenon 7 or later always means strong encryption.*
6.1 Basics

Encryption for zenon Runtime is available from version 7.0. It is not possible to communicate with earlier versions of zenon if encryption is switched on. Encryption does not impair any zenon functionality.

BASIC ENCRYPTION FROM ZENON 7.00

To use the strong encryption of the zenon network, note:

- The password is encrypted individually on each computer and stored in zenon6.ini. That means:
  - The password cannot be transferred by copying zenon6.ini to another computer.
  - If hardware components are changed, in the network adapter area in particular, the password may be invalid and need to be re-entered.
- Encryption must always be activated or deactivated off for all components involved in the zenon network. Communication between encrypted and unencrypted systems is not possible. Web Servers only act as a proxy computer and are not affected by encryption.
- If encryption is activated on a computer, it always applies for the projects of this computer with the Network active property active.

COMPATIBILITY

Encryption is not compatible with versions prior to zenon 7.00 SP0. That means:

<table>
<thead>
<tr>
<th>System 1</th>
<th>System 2</th>
<th>Communication</th>
</tr>
</thead>
<tbody>
<tr>
<td>zenon 7 encrypted</td>
<td>zenon 7 encrypted</td>
<td>Yes</td>
</tr>
<tr>
<td>zenon 7 unencrypted</td>
<td>zenon 7 unencrypted or zenon prior to version 7 unencrypted</td>
<td>Yes</td>
</tr>
<tr>
<td>zenon 7 encrypted</td>
<td>zenon 7 unencrypted or zenon prior to version 7 unencrypted</td>
<td>No</td>
</tr>
</tbody>
</table>

Errors (on page 49) are logged in the Diagnosis Viewer’s log file.
EXAMPLE

The following illustration shows an example of a network with Primary Server, Standby Server, two clients, one Web Server and two Web Clients. All devices are running zenon 7.00 SP0. The devices are configured as follows:

- Encryption is activated on the Primary Server using the Startup Tool (on page 45).
- Encryption is also activated on the Standby Server and client A via Remote Transport (on page 46) when Runtime files are transferred.
- Client B and Web Client B still communicate without encryption.
- On Web Client A, encryption is activated on the server using the Startup Tool (on page 45).
- Because the Web Server does not evaluate the data packets, but instead forwards these on immediately, it does not require encryption. In theory, it can also have an older version, and the Web Clients can nevertheless create encrypted connections.

This configuration leads to the following result:

- The Standby Server communicates successfully with the Primary Server.
- Client A can log in to the Primary Server and exchange data.
- Because client B sends unencrypted messages and these are rejected by the Primary Server because encryption is active, client B cannot communicate with the Primary Server and is therefore offline.
- Web Client A logs on to the server via the Web Server and can exchange data.
The unencrypted messages from Web Client B are forwarded from the Web Server to the Primary Server, but the server rejects these. Web Client B cannot communicate with the Primary Server and is therefore offline.

As soon as encryption via Remote Transport or the Startup Tool configuration on client B and via encrypt network communication on Web Client B is activated, these connections can also make connections to the Primary Server.

6.2 Activate encryption

Encryption can be activated in different ways:

- via the Startup Tool (on page 45) for the local computer and the Web Client
- via Remote Transport (on page 46)

HINT

For quick, easy activation of the encryption, it is recommended that the configuration is carried out on a computer using Remote Transport (on page 46).

6.2.1 Locally via the Startup Tool

To activate encryptions on the local computer or for the Web Client:

1. Open the zenon Startup Tool
2. Click on Application -> Options
3. The dialog for the settings of the zenon Startup Tool is opened
4. Select the 'Network configuration' tab

![Application settings window]

5. Check the checkbox Encrypt network communication

6. Enter the password and confirm this

7. Confirm the dialog by clicking OK

6.2.2 Via Remote Transport

Encryption can be activated on remote computers using Remote Transport. However, this is only possible if the Remote Transport connection is protected with a password.

To activate encryption using Remote Transport:

1. Click on the corresponding button in the Remote Transport toolbar

   or select, in the project's context menu: Set up Remote Transport> connection.
2. The dialog for setting up the connection is opened

![Establish connection dialog]

3. Enter the connection password or create one, if none has been set

4. **Activate the** Configure encryption of network communication **checkbox**

5. Click on **OK**.

6. The dialog for encryption of network communication is opened

![Encrypt network communication dialog]

7. **Activate the** Encrypt network communication **checkbox**

8. **Issue a password** (for criteria, see the network password encryption section (on page 48).)
   To quickly transfer the local configuration to other computers, the local password can first be read via Read local configuration.

9. Confirm the dialog by clicking on the **OK** button.
6.3 Network encryption password

The following is applicable for encryption of the communication in the network:

- **Minimum length**: 8 characters
- **Maximum length**: 20 characters.
  The displayed length is always set at 20 characters, in order to hide the actual length.
- **Permitted characters**:
  - **Letters**: A – Z; a – z
  - **Digits**: 0 – 9
  - **Special characters**
- **Characters that are not permitted**:
  - **Space**
  - **Enter key** (Return key)
- **Summary**: a password must contain at least 1 figure and 1 letter

6.4 Checklist for errors

In the event of errors, check:

- Do all computers have access to the network and does the naming resolution work between the computers?
- **Was the Network active property activated for the project in the Editor?**
- **Is zenon Runtime version 7.00 SP0 or higher being used?** (relevant if encryption is being used)
- Is - for projects with encryption - the configuration correct on all computers?  
  (USE_ENCRYPTION setting in zenon6.ini: The same for all computers, either 0, 1 or not present.)
- **Was the password set correctly?**
- **Was the hardware changed on one of the computers involved after the encryption has been configured?**
- **Does a ping work on a computer?**
• Yes: Network connection present, fault is with the communication.
• No: Check the network.

▶ Is it possible to connect to Telnet?
  • The connection is made: Both computers communicate at the same level. Check the password.
  • The connection is made and lost again: One computer communicates with encryption, one without encryption.
  • Faulty connection: zenon Runtime does not run on the target computer.

Note: Telnet must be installed as an extra on more recent Windows operating systems. Connection is generally made via port 1100.
The Telnet command is then: \texttt{open [IPAdresse] 1100}

▶ Are the required (operating system) functions available (primarily relevant for CE terminals)?
  • Non-existent functions lead to Runtime not being able to start.

▶ If the service provider or one of the algorithms is not available, an error message (on page 49) is written to the log file when Runtime is started.

Errors (on page 49) are logged in the Diagnosis Viewer’s log file.

\section*{6.5 Error messages}

Errors are either displayed in the output window of the zenon Editors or in pop-ups and/or in the log files of the Diagnosis Viewer.

\textbf{NO CONNECTION}

If a client has been configured with an incorrect encryption password (not the same as the password on the Primary Server) then this is evident from the following events:

▶ The Client is offline, although the Primary Server can be reached by pinging.
▶ The Primary Server writes error messages to the log file:

\begin{verbatim}
SysMod Error: Serialize in Object Project: [project name] Modul: [module number]
\end{verbatim}

or:

\begin{verbatim}
NET Error During Decryption [Error number]
\end{verbatim}
POP-UPS AND ERROR MESSAGES

Encryptions errors are notified by means of pop-ups (on page 50) (Pop-ups) and entries in log files (on page 53) or in the zenon output window (on page 52).

6.5.1 Error messages in pop-ups

STARTUP TOOL AND WEB CLIENT

The following error messages are output by the zenon Startup Tool as a pop-up for local encryption or by Encrypt Network Communication Tool for the configuration of the Web Clients. The messages that come directly from the Startup Tool or from the Encrypt Network Communication Tool are always in English; messages from Runtime itself are in the language that has been set.
Strong encryption of network communication

<table>
<thead>
<tr>
<th>Error message</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>The password has to be entered in both text boxes!</td>
<td>When configuring the encryption, the user has left one of the two input fields (Password or Password confirmation) empty.</td>
</tr>
<tr>
<td>The passwords you typed do not match. Please retype the password in both boxes.</td>
<td>The content of the input field for password confirmation is different to the content of the input field for the password.</td>
</tr>
<tr>
<td>The network password does not fullfill the password criterias!</td>
<td>The password entered does not meet the password criteria. The password criteria are displayed in the error message.</td>
</tr>
</tbody>
</table>
| - Minimum length = 8  
- Maximum length = 20  
- At least one character of the latin charset  
- At least one number  
- No spaces | |
| The network password could not be encrypted! | An error occurred when encrypting the network password. |
| The network encryption configuration in the file zenon6.ini is invalid. | When opening the Network configuration tab, it was established that the zenon6.ini file does not contain a valid configuration for the network encryption. A new configuration must be entered. |
| The network encryption password in zenon6.ini is invalid. | The password read in from the zenon6.ini file is invalid and must be reentered. |
| The password for the network encryption is invalid and must be entered again! | Message when Runtime starts if the password cannot be verified. |

**REMOTE TRANSPORT**

The following error messages are given by Remote Transport as a pop-up when the remote computer is encrypted.
## Strong encryption of network communication

Errors are displayed in the output window as messages:

<table>
<thead>
<tr>
<th>Error message</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>For configuring the network encryption, the Remote Transport connection must be protected with a password!</td>
<td>An attempt was made to configure remote encryption without securing the Remote Transport connection by means of a password.</td>
</tr>
<tr>
<td>You must enter the password in both input fields!</td>
<td>When configuring the encryption, the user has left one of the two input fields (Password or Password confirmation) empty.</td>
</tr>
<tr>
<td>The password confirmation does not match the password!</td>
<td>The content of the input field for password confirmation is different to the content of the input field for the password.</td>
</tr>
<tr>
<td>The password entered does not correspond to the password criteria.</td>
<td>The password entered does not fulfill the password criteria. The password criteria are displayed in the error message.</td>

<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>An error occurred when encrypting the password!</td>
<td>An error occurred when encrypting the password. If this error occurs during configuration via Remote Transport, a more detailed error message is written to the log.</td>
</tr>
<tr>
<td>An error occurred when decrypting the network password from zeon6.ini.</td>
<td>The password stored in zeon6.ini cannot be decrypted. If this error occurs during configuration via Remote Transport, a more detailed error message is written to the log.</td>
</tr>
<tr>
<td>The encryption configuration in zeon6.ini is not valid and must be reentered.</td>
<td>The password read off from zeon6.ini is invalid. The password must be entered again.</td>
</tr>
</tbody>
</table>

### 6.5.2 Error messages in the output window

Errors are displayed in the output window as messages:
### Message | Level | Description
--- | --- | ---
The server reports an error when compiling the data for the encryption configuration. | ERROR | The remote zenSysSrv reports an error when compiling the information for the encryption of the password for network encryption. The adapter information cannot be read off.

*** Configure the encryption of the network communication at the target system. |  | This message is at the start of the conclusion message after encryption has been configured on a remote device via Remote Transport. After this, there is a message in relation to the success of the remote configuration.

The server reports an error when the encryption configuration is changed. | ERROR | The remote zenSysSrv reports an error when the encryption configuration is saved to the remote device. The configuration was not saved.

The configuration was successfully saved on the server. | MESSAGE | The remote zenSysSrv reports that the encryption configuration was successfully saved.

The version of the remote zenSysSrv is too low. The encryption cannot be configured. | ERROR | An attempt was made to configure the encryption on a remote device, which has a zenSysSrv from a version prior to version 7.00 SP0. Encryption is only available from zenon version 7.00 SP0; an earlier version of zenSysSrv cannot therefore configure this.

---

#### 6.5.3 Error messages in log files

**ENCRYPTION**

Errors in encrypted network traffic are documented in log entries. The Error IDs of the error messages in the following summary are system or COM error codes. You can find more information in the MSDN library.
## Strong encryption of network communication

<table>
<thead>
<tr>
<th>LOG entry</th>

</tr>
<tr>
<td>Error During Adapter Info Query [Error ID]</td>
<td>ERRORS</td>
<td>An error occurred when the adapter information for encrypting or decrypting the network password for configuration via Remote Transport was read off.</td>
</tr>
<tr>
<td>NET Error During Decrypting Password: The Password is Invalid!</td>
<td>ERRORS</td>
<td>The password is no longer valid, because the initial data for computer-dependent encryption has changed. This error can be rectified by configuring the password again. The decryption process is usually cancelled before the validity of the password is checked, because the old password cannot be decrypted with the new encryption data. This leads to the &quot;NET Error During Password Decryption 0x80090005&quot; error, where instead of &quot;NET Error During Password Decryption The Password is Invalid!&quot; is displayed. Another consequence is that a password that is now invalid on the computer in question can lead to error messages when network packages are sent or received. The error message &quot;NET Error Cryptography Not Initialized!&quot; is written to the log file.</td>
</tr>
</tbody>
</table>

7. **zenon on the Terminal Server**

The zenon Runtime can also be used together with a terminal server solution.

Limitations:
The Editor cannot run on a terminal server.

Project simulation is not available for clients at the terminal server.

**Information**

Keep in mind that the name of the terminal client is resolved. That means: The name of the device that initiates the terminal connection is the name of the Clients for the zenon network.

Attention: Ensure that all corresponding ports have been unlocked when using a firewall.

Terminal server solutions are offered by several manufacturers. All tests with zenon were carried out using the Windows terminal server (Windows Remote Desktop Services).

**Attention**

When using zenon with a terminal server, it must be licensed with a Network dongle.

**SEVERAL INSTANCES OF RUNTIME**

Only one instance of zenon Runtime can be started on a computer at any time. This applies regardless of whether Runtime is started as an EXE file, a web client or as Runtime Control (OCX).

Exception: On the terminal server or terminal client, one instance of Runtime per user can be started as an EXE file, as a web client or as Runtime Control (OCX). Only 1 instance can run at any time within a user context.

### 7.1 How terminal servers work

With terminal servers, it is possible to provide data and applications centrally, regardless of the end device. Terminal servers make it possible to start several shell instances (desktops) that are separate from one another on the terminal server. If a client connects to the terminal server, a new shell instance is created and the client is assigned its own graphic user interface. The applications are executed on the terminal server itself and the data is saved on the terminal server. Input (via the keyboard, mouse etc.) and output (display, audio, etc.) is on the Client.

**Info**

Not all software is compatible with terminal servers.
7.2 Advantages and disadvantages

ADVANTAGES

► Only one computer (the terminal server) has to be maintained.
► Clients do not have to be very performant (Thin Clients).
► Clients can have different operating systems (Windows, Windows CE, Linux, Unix, MacOS, iOS, Android etc.).
► High degree of data security, because no data is saved on the Client.

DISADVANTAGES

► All started programs of all instances run on one computer (the terminal server).
  The computer:
  • must have sufficient computing power for all started programs.
  • must have sufficient RAM for all started programs.
► All interfaces have to be shared. E.g. network adapters, COM ports, parallel ports.
► The network load can be high with an appropriate number of Clients (such as transfer of graphic data).
► The screen resolution is defined by the client started first. If screens in different resolutions are to be used, this can be implemented on the terminal server by means of an entry in zenon6.ini (SERIALIZE=1). All screens are then calculated again for the client, which further increases the necessary performance for the terminal server.

7.3 Operation zenon at the terminal server

On a terminal server, operation is possible as:

► zenon Client possible without limitations
• zenon standalone systems only worthwhile and possible:
  • as a superordinate integration project to start several Client sub-projects
  • without drivers, database connections etc.
• zenon Primary Server not possible

**SCHEMATIC DISPLAY**

For example, the topology of a Terminal Server network with zenon could look as follows:

<table>
<thead>
<tr>
<th>Computer</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>A.</td>
<td>zenon Primary Runtime Server</td>
</tr>
<tr>
<td>B.</td>
<td>Terminal Server and n-fold Runtime Client</td>
</tr>
<tr>
<td>C.</td>
<td>Terminal Clients (input and output only)</td>
</tr>
</tbody>
</table>

### 7.4 Required settings

In order for zenon Runtime to be able to be started more than once on the terminal server, several settings must be made. The settings for registration, screen resolution and transfer service can be undertaken with the zenon Startup Tool.
Information

The following parameters are automatically set with registration via the Startup Tool:

- INI entries:
  - [TERMINAL]
    - CLIENT=1
    - SERIALIZE=1

- Registration of ZenSysSrv.exe as a service

GENERAL SETTINGS

1. Registration

Register the use on the terminal server via the zenon Startup Tool. Alternatively, you can configure the corresponding INI entries manually.

zenon6.ini entry:
The following entry must be added in zenon6.ini on the terminal server. On the Primary Runtime server no settings are needed.

[TERMINAL]
CLIENT=1

1: The Runtime can be started several times, all settings for the terminal server operation are automatically set by the Runtime.
0: The Runtime can only be started once. Operation on the terminal server is not possible. (standard setting)

2. Automatic adjustment of the screen resolution

Per default the first client at the terminal server defines the screen resolution. This setting can be amended on the terminal server with the following entry in zenon6.ini:

[TERMINAL]
SERIALIZE=1

1: Each client gets its own resolution.
0: The first client defines the resolution.

3. Transfer
The transport service (zensysrv.exe) must be registered and started as a Windows service, not as a standard EXE file. This setting is automatically set when registering via the Startup Tool, but can also be set manually.

**Manual setting:**

a) Start the program from the command line interface with the `-service` option.
   
   For example: `C:\Programs (x86)\COPA-DATA\zenon711\zensysrv.exe -service`

b) Then start the Windows Service Manager. The service will be started automatically during every computer restart.

**Note:** The setup always registers the transport service as a standard EXE. Therefore the transport service must be re-registered as a Windows service after every reinstallation.

4. **Runtime folder**

   All users must have write access to the Runtime folder. All Windows users (Windows users: *All*) in the Windows Explorer must have complete access to the Runtime folder and all its subfolders.

5. **Rename zenprocess.exe**

   If a user terminates Runtime during terminal server operation, `zenprocess.exe` also terminates the Runtimes of all other users. In order to prevent this, the file `zenprocess.exe` must be renamed in terminal server operation. `zenprocess.exe` is then no longer started. You can find the file in the zenon installation folder.

**SELECTIVE RELOADING OF SINGLE PROJECTS**

Projects can also be synchronized selectively. In this case clients only reload projects if project changes exist. To activate the selective reloading:

1. open the file `zenon6.ini` with a text editor

2. go to area `[TERMINAL]`

3. edit or create entry: `CLIENT_NO_FILE_ALIGN=`

4. possible values:

   0: Projects are always reloaded by all clients

   1: selective synchronization active. Only the zenon client which is started in the console session of the terminal server synchronizes the Runtime files with the zenon server
After synchronizing the Runtime files the console client writes file `reloadindicator.tmp` in the directory which contains file `project.ini` of the program. The session clients at the terminal server check every 10 seconds whether this file is available. Does it exist and is its file time stamp newer than the date of the last reload, a session client reloads automatically.

**ENTRY IN ZENON6.INI FOR SELECTIVE RELOAD**

```ini
[TERMINAL]
CLIENT=1
CLIENT_NO_FILE_ALIGN=1
SERIALIZE=1
```

### 7.5 zenon Remote Desktop versus Terminal Server

The terminal server solution is different from zenon Remote Desktop most of all due to the following points:

<table>
<thead>
<tr>
<th>zenon Remote Desktop connection</th>
<th>Terminal server connection</th>
</tr>
</thead>
<tbody>
<tr>
<td>All connected stations always see one and the same desktop. If e.g. one user starts a program, all see the same program, the same mouse cursor, the same keyboard input, etc.</td>
<td>Each connected station has its own desktop - an own instance. Only it sees, what happens there. Mouse actions and keyboard inputs only affect this one instance.</td>
</tr>
<tr>
<td>That also means: In each instance a program can be started separate, e.g. a text editor. The program then runs on the terminal server several times and therefore needs more resources.</td>
<td></td>
</tr>
</tbody>
</table>

### 8. Administering and checking network topology

The network topology is displayed in a separate project manager tab.

It consists of three areas:
- Topology tree (on page 63) (top left): shows active projects; the global project is not displayed
- Event tree (on page 64) (top right): only the result is displayed; represents the topology tree of a selected computer
- Computer list (on page 65)(bottom): List display and configuration of computers in the network

8.1 Topology tree

The topology tree displays active projects in hierarchical form.
Administering and checking network topology

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Project name</td>
<td>Is defined in the project tree tab and cannot be changed here.</td>
</tr>
<tr>
<td>Network active</td>
<td>Displays whether the network option is active for this project. The setting can be changed via the Network active property.</td>
</tr>
<tr>
<td>Server 1</td>
<td>Displays the Primary Server defined for this project. The setting can be changed via the context menu, the symbol in the tool bar or the Server 1 property.</td>
</tr>
<tr>
<td>Server 2</td>
<td>Displays the Standby Server defined for this project. The setting can be changed via the context menu, the symbol in the tool bar or the Server 2 property.</td>
</tr>
</tbody>
</table>

**TOOLBAR AND CONTEXT MENU**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set computer as Primary Server</td>
<td>Defines the computer highlighted in the computer list (on page 65) as the Primary Server for the project highlighted in the tree.</td>
</tr>
<tr>
<td>Set computer as Standby Server</td>
<td>Defines the computer highlighted in the computer list (on page 65) as the Standby Server for the project highlighted in the tree.</td>

</tr>
</tbody>
</table>

### 8.2 Result tree

The result tree represents the project tree of the computer selected in the computer list (on page 65) from the project, which is set as a start project for the selected computer and displays these project settings.

The result tree is empty if:

- The start project of the selected computer was not found
- More than one computer in the list was selected
### Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Project name</strong></td>
<td>Projects that are assigned to the selected computer.</td>
</tr>
<tr>
<td><strong>Role</strong></td>
<td>Role of the computer:</td>
</tr>
<tr>
<td></td>
<td>- Primary Server</td>
</tr>
<tr>
<td></td>
<td>- Standby Server</td>

</tr>
</tbody>
</table>

### 8.3 Computer list

The computer list shows all computers that have been added and allows them to be configured. The list relates to the workspace and is saved in the workspace file (*.wsp6).
### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Computer name</strong></td>
<td>Name of the computer. Can be changed by:</td>
</tr>
<tr>
<td></td>
<td>- Click in the cell: Clicking on the ... button opens a drop-down list of the computers currently available in the network.</td>
</tr>
<tr>
<td></td>
<td>- <em>Edit computer</em> entry in the context menu or the tool bar</td>
</tr>
<tr>
<td></td>
<td>- <em>Computer name</em> property.</td>
</tr>
<tr>
<td><strong>Start project</strong></td>
<td>The start project assigned to the computer Can be changed by:</td>
</tr>
<tr>
<td></td>
<td>- Click in the cell: Select from drop-down list.</td>
</tr>
<tr>
<td></td>
<td>- <em>Set start project</em> entry in the context menu or the toolbar Sets the project selected in the topology tree (on page 63) as the start project.</td>
</tr>
<tr>
<td></td>
<td>- <em>Start project</em> property.</td>
</tr>
<tr>
<td><strong>Start project Runtime folder</strong></td>
<td>Folder for project files on the target computer. The files of the start project are saved in this folder. All other projects relating to this correspond to the structure of the Runtime folder set up on the local computer.</td>
</tr>
<tr>
<td></td>
<td>For example:</td>
</tr>
<tr>
<td></td>
<td>Start project Runtime folder:C:\Projects\Top = location where start project is stored.</td>
</tr>
<tr>
<td></td>
<td>Sub projects are stored in C:\Projects.</td>
</tr>
<tr>
<td></td>
<td><strong>Hint</strong>: Use the project name as folder name in order to create the same structure as on the engineering computer automatically.</td>
</tr>
<tr>
<td></td>
<td>The Start project Runtime folder can be changed by:</td>
</tr>
<tr>
<td></td>
<td>- double clicking on the computer: Opens computer configuration dialog (on page 68).</td>
</tr>
<tr>
<td></td>
<td>- Click in the cell: Manual entry possible.</td>
</tr>
<tr>
<td></td>
<td>- <em>Start project Runtime folder</em> property.</td>
</tr>
<tr>
<td><strong>Result of test</strong></td>
<td>Shows the result of the topology test.</td>
</tr>
<tr>
<td></td>
<td>- <strong>OK</strong>: All projects are free of errors.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Error detected</strong> - For details see detail view! One or more projects have an error.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Critical error detected</strong> - For details see the detail view! One or more projects have a critical error.</td>
</tr>
</tbody>
</table>
A project has a serious error. Serious errors halt further testing.

- Not tested, because there is a serious error in the structure: The computer was not fully tested, because the test was ended due to a serious error.

Detailed error messages (on page 69) are displayed in the result tree.

### TOOLBAR AND CONTEXT MENU

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add computer...</td>
<td>Opens the Configure computer dialog (on page 68) in the network.</td>
</tr>
<tr>
<td>Edit computer...</td>
<td>Opens the dialog to configure the computer (on page 68) in the network for these computers.</td>
</tr>
<tr>
<td>Delete computer</td>
<td>Deletes computer from the topology after requesting confirmation.</td>
</tr>
<tr>
<td></td>
<td><strong>Attention:</strong> Deletion of the Primary Server or Standby Server leads to serious errors in the topology.</td>
</tr>
<tr>
<td>Set start project</td>
<td>Sets the project selected in the topology tree (on page 63) as the start project.</td>
</tr>
<tr>
<td>Copy Runtime files from all projects on the computer</td>
<td>Copies all projects valid for the selected computer to the target computer. The result is displayed in the output window.</td>
</tr>
<tr>
<td>Help</td>
<td>Opens online help.</td>
</tr>
</tbody>
</table>
8.3.1 Computer network configuration dialog

The following data is necessary to configure the computers:
<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Computer name</td>
<td>Clicking on the ... button opens a drop-down list of the computers currently available in the network.</td>
</tr>
<tr>
<td>Start project</td>
<td>Selection of the start project from a drop-down list.</td>
</tr>
<tr>
<td>Start project</td>
<td>Folder for project files on the target computer. The files of the start project are saved in this folder.</td>
</tr>
<tr>
<td>Runtime folder:</td>
<td>All other projects relating to this correspond to the structure of the Runtime folder set up on the local computer.</td>
</tr>
<tr>
<td></td>
<td><strong>Hint:</strong> Use the project name as folder name in order to create the same structure as on the engineering computer automatically.</td>
</tr>
<tr>
<td></td>
<td>For example: Project name = I-Project at Start project Runtime folder enter: C: \ Projects \ I_Project</td>
</tr>
<tr>
<td></td>
<td>The sub-projects in relation to this path are stored at C: \ Projects \ Projektname, for example: The project name is SubProject1, then the Runtime folder for this is C: \ Projects \ SubProject1.</td>
</tr>
<tr>
<td></td>
<td>Requirement: The Runtime folders are left at their default settings and the projects were created at one file level.</td>
</tr>
<tr>
<td></td>
<td>If this is not the case, it may be the case that subprojects cannot be copied, because the relative folder cannot be created from the start project.</td>
</tr>
<tr>
<td></td>
<td>Example: The integration project has the following set up as a Runtime folder: C: \ Workspace \ Projects \ I_Project. The sub project has the following set up as a Runtime folder: C: \ Subproject. The start project Runtime folder is set to C: \ Project. The sub project cannot be transferred, because the relative folder would be .. .. \ Project. This does not work, because the Runtime folder for the sub project would be below C.</td>
</tr>
<tr>
<td></td>
<td><strong>Solution:</strong> Set the Runtime folder project property correctly. It is best to do it so that the Runtime folder is at the same level for all projects.</td>
</tr>
</tbody>
</table>

### 8.4 Error messages from topological testing

The topology test is always carried out if settings concerning the topology change. The effect of each change can be observed immediately this way. The topology is also tested if the topological view is changed.
TESTS CARRIED OUT

- Is the project defined in the project tree available in the project tree?
- Was a Primary Server defined?
- Were different computers defined for Primary Server and Standby Server?
- Can the client achieve its Primary Server/Standby Server?
- Can the Primary Server reach its clients?
- Can the Standby Server reach its clients?
- Is the Primary Server available for a project in the topology?
- Is the Standby Server available for a project in the topology?
- Is a computer included more than once in the path from Client to the Primary Server?

NOT TESTED:

- Is a client only updated on one path by the Primary Server or do several paths exist?

CLIENT TO SERVER

- Does the client reach its Primary Server via the Primary Server’s chain?
- Was a computer that routes switched to its Standby Server?

Info: The server must also be be able to be reached by the client via the project’s Standby Server that routes.

ERROR MESSAGES

Errors that are recognized during the topology test are displayed in the result tree (on page 64) in the test result column.
<table>
<thead>
<tr>
<th>Errors</th>
<th>Reason</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>The start project is unknown!</td>
<td>Start project cannot be found.</td>
<td>Correct project configuration or include missing project in the workspace.</td>
</tr>
<tr>
<td>The computer is entered as a server and standby!</td>
<td>Server and Standby Server must be different computers.</td>
<td>Define different computers as Server and Standby Server.</td>
</tr>
<tr>
<td>No computer is entered as server!</td>
<td>The project is a network project but no server was configured.</td>
<td>Define a computer as a server.</td>
</tr>
<tr>
<td>The project is not started on computer (name)! However it is necessary because higher hierarchic levels need access to it.</td>
<td>The project is not loaded on the computer stated. The project is however routed via this.</td>
<td>Adapt topology or start project for the computer or deactivate the Routing active property.</td>
</tr>
<tr>
<td>Circular access to the server: The computer (name) redirects to the client (name)!</td>
<td>The routing path from the client to server goes around in a circle. The computer that acts as a node redirects to the client.</td>
<td>Adapt topology or start project for the computer or deactivate the Routing active property.</td>
</tr>
<tr>
<td>Circular access to the standby: The computer (name) redirects to the client (name)!</td>
<td>The routing path from the client to the standby goes around in a circle. The computer that acts as a node redirects to the client.</td>
<td>Adapt topology or start project for the computer or deactivate the Routing active property.</td>
</tr>
<tr>
<td>The computer (name) is not included in the list of computers</td>
<td>Computer is missing in the list of computers for the topology.</td>
<td>Add computer to topology.</td>
</tr>
<tr>
<td>Not checked because there is critical error in the topology</td>
<td>No test was carried out due to a serious error.</td>
<td>Rectify serious error.</td>
</tr>
<tr>
<td>Circular access path: (computer names)</td>
<td>The routing path from the client its the server/standby goes around in a circle. The &quot;computer names&quot; field contains the names of the computer that are affected. Structure: The first computer is always the client. The separator between the computer names indicates whether the following</td>
<td>Adapt topology or start project for the computer or deactivate the Routing active property.</td>
</tr>
</tbody>
</table>
Redundancy in zenon ensures that processes are not interrupted even in the event of a failure of the Primary Server and that no data is lost. In zenon, we speak of **seamless redundancy**.

Seamless redundancy means that the time period between the failure of the Primary Server and detection of the failure is protected from data loss. This is implemented as follows:

- The Standby Server detects the failure of the Primary Server and automatically takes on the complete functionality thereof.
- In order to avoid data loss in the time period between the server failure and the detection of the failure, the standby always buffers all data.
- After a failure of the Primary Server, this buffer is merged with the last data from the server and the new incoming data, so no data can be lost.

### Table: Circular Access Path

<table>
<thead>
<tr>
<th>Condition</th>
<th>Description</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Circular access path exists from server to client!</td>
<td>The server is found according to the node when searching for the client computer.</td>
<td>Adapt topology or start project for the computer or deactivate the Routing active property.</td>
</tr>
<tr>
<td>The server (name) does not reach this client!</td>
<td>The path is not closed from the stated server to the client. The client is included in the client list on the server but is not updated. (The blue dots do not disappear on the client.)</td>
<td>Adapt topology or start project for the computer or deactivate the Routing active property.</td>
</tr>
</tbody>
</table>

### Example

For example: Computer1+Computer2 > Computer3
Info

Redundancy is not supported by zenon Operator.

An Operator Client can connect to a redundant project however. For this, the following applies:

- Connection to the server works; connection to the standby is not possible.
- An Operator Client can only connect to Supervisor Server projects, which each contain only one driver per driver type. If the project on the server contains several drivers of one type, such as two S7 TCP/IP drivers, then the loading of the project is canceled.

CONFIGURATION OF SEAMLESS REDUNDANCY

For the configuration of seamless redundancy for a zenon project, you only need two simple, conventional computers.

Define, in the project properties:

1. A computer that is to be the Primary Server (on page 21) for the project
2. A computer that is to be the Standby Server (on page 75) for the project

PROCESS OF SEAMLESS REDUNDANCY

- One computer is the Primary Server and one computer is the Standby Server for a project.
- As in a normal Client-Server model, the Primary Server has ownership of all data.
- The Standby Server acts outwardly to the user like any other computer on the network that has started the project.
The Standby Server independently records all historical data such as alarms, events and archives and synchronizes other data (recipes, users, etc.) with the Primary Server.

If the Primary Server fails, the Standby Server upgrades itself and takes over its tasks.
- In order to avoid data loss in the time period between the server failure and the detection of the failure, the standby always buffers all data. After a failure of the Primary Server, this buffer is merged with the last data from the server and the new incoming data, so no data can be lost.
- All Clients connect to the new Primary Server.
- If the original Primary Server goes back online again:
  - It connects to the current Primary Server
  - Synchronizes all data
  - Becomes the Primary Server itself again
- The original Standby Server becomes the Standby Server again.
- All Clients connect to the new Primary Server.

Info

Project changes need only be entered on the Primary Server; the standby server and the connected clients automatically synchronize online data. This ensures that the project status is the same on all computers.

SOFTWARE REDUNDANCY AND HARDWARE REDUNDANCY

With redundant systems in zenon, a distinction is made between software redundancy (on page 75) and hardware redundancy (on page 75).

CIRCULAR REDUNDANCY

zenon circular redundancy (on page 82) is a special form of redundancy that allows seamless redundancy for several projects with a low amount of hardware being used and very simple configuration.

ZENON REDUNDANCY AND STRATON REDUNDANCY

You can find details on the combination of zenon redundancy and straton redundancy in the straton Runtime manual.)
9.1 Setting up the Standby Server

To set up the Standby Server:

1. Open, in the project properties in the Editor, the Network group.

2. Enter, in the Server 2 property, the name of the computer that is to serve as the Standby Server for the project. (the computer must have a connection to the PLC.)

You can enter the computer name:

a) By selecting from the drop-down list after clicking on the ... button
b) Manually

Select, in the Redundancy type property, the desired redundancy form from (on page 75) the drop-down list:

9.2 Types of redundancy

For redundant systems with zenon, a distinction is made between:

- **Software redundancy**: Only the Primary Server communicates with the controller in two directions (write and read). The Standby Server communication is read-only.

- **Hardware redundancy**: PLCs are also designed as redundant. The Standby Server communicates two ways with the controller that is designed as redundant.

You can find the selection of this in the configuration of the Standby Server (on page 75).
SOFTWARE REDUNDANCY

The following components are required for software redundancy:

- A controller
- Two redundant computers (Primary Server and Standby Server)

In operation, the Primary Server communicates with the controller in two ways, the Standby Server communicates with the controller as read-only and synchronizes its data from the Primary Server.

In the event of a failure of the Primary Server:

- The Standby Server becomes the new Primary Server
- Seamless redundancy (on page 72) ensures that all data is complete without omissions, including data from the time between the failure and the switch
- The new Primary Server communicates with the PLC both ways

HARDWARE REDUNDANCY

The following components are required for hardware redundancy:

- Two redundant controllers
- Two redundant computers (Primary Server and Standby Server)

In operation, the Primary Server communicates both ways with the first controller; the standby communicates with the controller both ways.
The Standby Server synchronizes with the Primary Server; the second PLC synchronizes with the first PLC.

In the event of a failure of the Primary Server or the first controller:

- The Standby Server becomes the new Primary Server
- Seamless redundancy (on page 72) ensures that all data is complete without omissions, including data from the time between the failure and the switch
- The Primary Server communicates both ways with the second controller
9.3 Special setups in the communication between Primary Server and Standby Server

Note the rules in the following setup:

- The Primary Server has failed
- The Standby Server has taken on its role
- The original Primary Server is restarted
- The original Primary Server gets all Runtime files from the current Primary Server (originally the Standby Server)

In exceptional cases, there may be conflicts if:

1. Changes have only been made to the project of the original Primary Server that has been stopped
2. It is not clear, due to network problems, which computer is the Primary Server.

1. PROJECT CHANGES WITH THE PRIMARY SERVER STOPPED

If you, during the time in which Runtime is stopped on the original Primary Server, make changes to the project and introduce these before synchronizing on this (stopped) computer, these changes are overwritten again as soon as the original Primary Server gets the data from the current Primary Server (the original Standby Server).

To prevent this: Introduce the amended data onto the Primary Server (configured Standby Server) as well, before starting the original (configured) Primary Server.

2. SERVER ROLE NOT CLEAR DUE TO NETWORK PROBLEMS

In exceptional cases, it may happen that both computers are the Primary Server. The cause of this can be, for example, a loss of network connection due to a switch failure, a disconnected network cable etc. In this case, the communication between the Primary Server, Standby Server and Clients depends on the error screen.

If, with this setup, the error screen is resolved and both servers communicate with each other again (at this time), then the original (configured) server has data sovereignty. That means: The standby server’s more recent data could be overwritten.

To prevent this:
1. Always check the role distribution with the current Primary Server (SYSDRV.chm::/25959.htm) system variable:
   You will see the role that Runtime has and discover duplicate Primary Servers.

2. End zenon Runtime on the Primary Server that lost the network connection.

3. Set up the network connection again.

4. Restart zenon Runtime on this computer.

5. Runtime then starts the project with the computer as a Standby Server, updates its data and only then switches back to the Primary Server role.

**Hint:** Monitor the network connection with the Redundancy Management Tool (on page 84).

⚠️ **Attention**

*PNG* graphics files cannot be overwritten if they are currently being displayed in Runtime.

*Background:* The Runtime protects opened *.png files against overwriting.

*Solution:* Before Remote Transport is initiated, it must be ensured that screens with the *.png file are not being displayed in Runtime and that the file is also not being used by another program. This also applies for the reloading of amended Runtime files. The Runtime sync in the network does not work for a *.png screen if this is switched on a zenon computer that is involved in the process (standby server, client).

### 9.4 Integrated evaluation methods for redundancy switching

In the dominant network, the Standby (as the Primary Server) regularly sends a telegram to the (dominant) Server 1, so that this - as soon as it receives a connection - can take on its role again. In an evaluated network, no telegram is sent any more in this case.

If there are two servers, the evaluation decides on the role.

**USE OF DOMINANT BEHAVIOR IN STRATON**

- A driver can delay upgrading to a server on the dominant server. This function is no longer present in an evaluated network with servers that have equal rights.
- Archives also receive an extra byte per entry on the Standby Server as well as on the Server 2. This ensures that the archives are different and are included in a synchronization.

- Furthermore, the network topology for the drivers uses the terms Dominant and Standby as well as the roles as Server or Standby. However only the role is evaluated, so no change is therefore necessary.

- straton is supplied with information on the label and role via CStratonVM::UpdatePrjSTates. The only thing that is evaluated is whether a computer is configured as a Standby and not the Primary Server. In this case, straton is also not active.

### 9.5 Configuration of the evaluation

A dialog is called up for the "Evaluations" property, which shows the variables used in a list with all the weights and criteria/limits.

The list can sort in the columns and filter; the width and sequence of the columns can be amended. These settings are retained during an editor session; the default is sorting according to the variable name.

A separate button resets all filters; the list is then refilled. The selected line should be retained.

T6 variable selection and editing in the list

In the parameter dialog, new variables are selected by means of a selection dialog, weight and limit are edited directly in the list, a combo box is shown for the criteria.

Editing starts with a click on the element or with "F2"; a mouse click next to the element or "Enter" accepts the change, "Esc" cancels without accepting the changes. With comma values, "," or ",", can be entered, all values are displayed according to the zenon variables (decimal point, BOOL). If a filter is active, the line can disappear after editing if it no longer meets the criteria of the filter; if the column is sorted, the line moves to its new position.
The "Remove" button deletes the selected line; several lines can also be removed by means of variable selection. Newly inserted variables are created with the default values (weight 100, comparison "not used", limit 0); if a filter is active they may not be shown.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
</table>
| Name of the variable | List of the variables that can be used for the evaluation.  
Note: A maximum of 200 variables can be used for the redundancy evaluation. |
| Weighting         | Input range: 0 - 1000  
Default: 100 |
| Comparison        | Drop-down list:  
- not used  
- Only status OK / Value OK  
- Values from limit are OK  
- Values up to limit are OK  
Default: not used |
| Limit             | Default: 0 |
9.6  zenon circular redundancy

zenon circular redundancy allows seamless redundancy for several projects with a low amount of hardware being used.

Two computers are normally required for each redundant project: one computer as the Primary Server and one computer as the Standby Server. 3 projects would thus require 6 computers. Just three computers are sufficient for implementing three projects with zenon circular redundancy. Another computer is added for each further project. For this, zenon combines multi-project administration (on page 25) with seamless redundancy (on page 72).

CONCEPT OF CIRCULAR REDUNDANCY

Circular redundancy uses the possibility of multi-project administration. Several projects can run simultaneously on one computer. Each computer is the Primary Server for a project and the Standby Server for a second "neighboring project" and can also be the Client for further projects. This results in a circle. Instead of four computers, for example, and licenses for two projects, six for three or eight for four, you only need half of that.
Redundancy

Topology with three projects

- Computer 1 is the Primary Server for Project A and Standby Server for Project B.
- Computer 2 is the Primary Server for Project B and Standby Server for Project C.
- Computer 3 is the Primary Server for Project C and Standby Server for Project A.

The circle is closed!

- Each computer can be a Client for the other projects at the same time.
- Expense: 3 computers and 3 Runtime licenses

Info

An integration project (on page 27) is needed to start more than one project on a computer.

Normally you would need six computers and six Runtime licenses in this example. zenon circular redundancy is of course not limited to three projects, but can connect as many projects as desired in a circle. The fact that the computers can also be clients for other projects allows easy implementation of a low-cost, fail-safe, highly-available production line.

TIME SYNCHRONIZATION FOR ZENON CIRCULAR REDUNDANCY

If zenon time synchronization (on page 13) is active, the Standby Server and clients always receive the current time from the Primary Server. This makes no sense when using zenon circular redundancy, because the individual PCs are Primary Server and Standby Server at the same time. Computer 1 for example, would thus obtain the time from computer 2, computer 2 would obtain it from computer 3 etc.
**Recommendation:** In this case, deactivate the zenon time synchronization and carry out external time synchronization. You can find instructions for this in Time synchronization in the network (on page 13).

### 10. Redundancy Management Tool

The **Redundancy Management Tool** monitors the network adapter and its connection to the network. If the device loses the connection to the network - e.g. by removing the network cable, the **Redundancy Management Tool** stops the Runtime. This process can be canceled by the operator within a configurable period of time. If the connection to the network is reestablished, the **Redundancy Management Tool** restarts the Runtime.

**START AND CONFIGURATION**

The **Redundancy Management Tool** can be configured via a dialog or via command line.

To open the dialog, there a three possible ways:

- From the Windows start folder: Start -> All programs -> COPA-DATA -> Tools 7.11 -> Redundancy Management Tool
- Via the Startup Tool: Tools -> zenon_redman
- Direct start of the file `zenon_redman.exe` from the zenon program folder

After the start the **Redundancy Management Tool** is also displayed as symbol in the right area of the Windows task bar. Double click on the symbol to open the configuration dialog:
<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>State</td>
<td>Status of the network adapter.</td>
</tr>
<tr>
<td>Network adapter connection state</td>
<td>Information about the status:</td>
</tr>
<tr>
<td></td>
<td>‣ Connected: Connection to the network established.</td>
</tr>
<tr>
<td></td>
<td>‣ Disconnected: Connection to the network interrupted.</td>
</tr>
<tr>
<td>Runtime state</td>
<td>Status of the zenon Runtime</td>
</tr>
<tr>
<td></td>
<td>‣ Running: Runtime is running.</td>
</tr>
<tr>
<td></td>
<td>‣ Stopped by Redundancy Management Tool: Runtime was closed by the tool.</td>
</tr>
<tr>
<td></td>
<td>‣ Stopped: Runtime is not running.</td>
</tr>
<tr>
<td>Settings</td>
<td>Settings.</td>
</tr>
<tr>
<td>Monitored network adapter</td>
<td>Selection of the network adapter which should be monitored from the drop-down list. List displays all found adapters in the device.</td>
</tr>
<tr>
<td>Runtime shutdown delay</td>
<td>Setting of the delay time in seconds before the Runtime is closed. In this period of time the operator can cancel the closing of the Runtime.</td>
</tr>
<tr>
<td></td>
<td>‣ Maximum value: 2147483647 s.</td>
</tr>
<tr>
<td></td>
<td>Values above this are interpreted as 0.</td>
</tr>
<tr>
<td>Apply</td>
<td>Applies the settings, writes values in the INI file and closes the dialog.</td>
</tr>
</tbody>
</table>

**INI FILE**

At the configuration via the dialog, file `RedMan.ini` is created in path `%ProgramData%\COPA-DATA\System`. It contains the following entries.
## COMMAND LINE

The **Redundancy Management Tool** can also be started via the command line.

Possible parameters:

- `ADAPTER='Name'`: Defines the network adapter which should be monitored.
- `DELAY='Seconds'`: Defines the waiting time after a connection loss. Maximum value: 2147483647. Values above this are interpreted as 0.
- `HELP,?:` Displays help about the command line parameters

---

### Information

*At the configuration via command line:*

- these settings are taken over directly
- the configuration is deactivated in the dialog
- no INI file is written
IN THE RUNTIME

During the Runtime the Redundancy Management Tool monitors continuously the network connection. If the connection is interrupted, the Redundancy Management Tool displays a warning and closes the Runtime after the configured delay time.

As soon as the connection is available again, the Redundancy Management Tool restarts the Runtime.

Click on button Cancel to halt the countdown and prevent the closing of the Runtime. If the connection is reestablished, the dialog is displayed again when the connection fails again. The user can cancel again or let the tool close the Runtime.

The current status of the connection and the Runtime is also always displayed in the configuration dialog.
ERROR HANDLING

ERROR MESSAGES

Error messages are displayed by pop-up messages.

<table>
<thead>
<tr>
<th>Message</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>GetAdapterAddresses not supported on this platform! Error code '%u'!</td>
<td>Operating system version is not supported</td>
</tr>
<tr>
<td>GetAdapterAddresses did not return information about network adapters. Error code '%u'!</td>
<td>No network adapter found.</td>
</tr>
</tbody>
</table>

LOG FILES OF THE DIAGNOSIS VIEWER

In the log file of the Diagnosis Viewer the following is documented:

<table>
<thead>
<tr>
<th>Entry</th>
<th>Debug Level</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Network link '%s' down for '%u' seconds. zenon Runtime will be terminated.</td>
<td>Errors</td>
<td>Network connection failed: The Runtime is closed.</td>
</tr>
<tr>
<td>Network link '%s' is up. Restarting zenon Runtime now.</td>
<td>Information</td>
<td>Network connection available again: The Runtime is restarted</td>
</tr>
</tbody>
</table>

11. Routing

For routing, the packets of subordinate projects are sent to the first client project (FCP) in the branch. The computer acts as node computer and can route packets. Thereby all network packets from the outside use this computer. This setting can lead to bottlenecks and influences the possible network topology. It is only worthwhile using it in special network setups, e.g. for WAN networks or routed networks.

- Example:
  If, in a setup consisting of several computers, not all computers can reach the others, a computer can act as a router.
Technical implementation:
The Server 1 and the Server 2 of the subordinate projects are amended on that of the FCP; this is the Server 1/Server 2 active in runtime.

GENERAL NOTES ON ROUTING

BASIC RULES

Two basic rules must be noted when configuring network structures with routing. If one of these rules is not adhered to, communication problems or other undesired effects may occur depending on the respective structure.

- **Rule 1: Server and levels**
  A PC that acts as a server may only act in one level (circular redundancy) act as a server or Standby several times. It must not be defined as a server a level above or below.

- **Rule 2: Standalone**
  If the start project is a single-user project, only one single level below can be used for network projects.

CLIENT SENDS TO A SERVER

- The client sends the packet to the server active in the project in Runtime.
- If the project on this computer is not the server, the packet is sent until it arrives at the server.
- This functionality is not affected by an integration project.

SERVER SENDS TO A CLIENT WITH ROUTING

1. If the server has a direct client connection to the client, the packet is sent there.
2. If there is no client connection to the target computer, the server sends the packet to all computers on which the project is running for which it acts as a server.
3. If the node has a direct client connection to the client, the packet is sent there.
4. If the computer works as a node, then the packet is sent to all computers which have connected to the node computer. It the target computer is also the source computer, the packet is not sent any further.
5. The procedure is continued at point 3.

**Note:** Points 2 and 4 are only carried out if routing is active on these computers.

---

**Information**

The Server and Standby need not correspond to what has been configured on the client computers, otherwise they may change themselves depending on the topology of the respective computer.

---

**WHAT IS A CLIENT CONNECTION?**

A network service connection is labeled as a client connection if it is made to the server or standby handling the process by a client. This is recognizable in that there is a connection to port 1100 on the target computer.

---

**Attention**

It is not guaranteed that a pure client computer added to a functional, defined topology will work. It is possible that some projects cannot be reached by the server due to routing on client computers in particular.

---

**RULES FOR ROUTING BEFORE ZENON VERSION 6.50:**

1. The first client network project of a branch on a PC defines the server and standby for all subordinate projects in the branch. This also applies:
   - If a subordinate project on this PC server or standby were
   - for projects that do not really have a Standby Server

2. If the subordinate project is not a network project or is not a server, the branches of the subprojects of the start project are considered in parallel. Different computers can therefore be servers for the subprojects. The rules from item 1 apply for the branches.

3. Single user projects are not taken into account for the topology, with the exception of the start project.

4. If the start project is not a server (i.e. single user, client or standby not handling the process), routing is not activated in the network service. This only affects the direction from the server to the client.
RULES FOR ROUTING FROM ZENON VERSION 6.50:
The Routing active property is deactivated as standard from version 6.50 onwards.

WITHOUT ROUTING
If the Routing active property is not active for the start project on the computer, routing does not take place. Each project then connects directly to the corresponding computer, where it is the server. The computer is then not a node and packets are also not routed from here.

WITH ROUTING
The rules as they were prior to 6.50 remain valid.

Exception:
- A project that is a server or standby on the computer remains a server or standby, even if the superordinate project uses another server or standby.

CHECKING THE ROUTING
To check the routing settings, use the procedure from "Administering network topology (on page 62)".

12. Authorization in the network

A network project can be operated from all stations in the same way with the basic settings.

Operating here means actively intervening in the process, such as:
- Write values
- Write recipes
- Alarms: Acknowledge
- etc.

There is thus the danger that two users on two different stations want to set different values for the same variable at the same time.
In this case:

- Both actions are executed
- The values that is entered last overwrites all previous ones

In zenon you have the possibility to allow operation of the project only from one station at the time. In this case the operator has to get the authorization, before he can operate the project. Opening screens, as well as read access to lists such as AML, CEL, recipes, etc. is possible on each station as always.

**Information**

*Operating authorizations for projects without a network can be implemented by evaluating a binary variable for the project property Operation lock.* For details, see the *Operating authorizations* chapter in the *Project administration and workspace manual*.

**PROCEDURE**

The following is applicable if the Authorization in network active property is active:

- Authorization must be obtained if active operation takes place.
- If operation is blocked by another computer, a dialog is opened on the compute that is blocking it.
- The user that is blocking it can approve the authorization or keep it blocked.
- If there is no response, the authorization is approved after a pre-set time-out.
- If an interruption in the network connection is recognized, then the authorization for this computer is reset.

For details see chapter:

- Configuring authorization (on page 93)
- Authorization in Runtime (on page 95)

**SYSTEM VARIABLES FOR AUTHORIZATION**

The system variables inform you about authorization:
Authorization in the network

- **Computer with authorization:** Name of the computer that has the authorization (string)
- **Authorization present for this computer:** Computer has authorization (Bool)
- **Authorization not granted:** Computer requests authorization, but does not receive it (Bool)

For details, see the Network messages from the system driver (on page 115) chapter.

### 12.1 Configuring authorization

To enable authorization in the network, you must:

- Activating authorizations and setting time-outs
- Configuring functions for getting and approving operating authorizations in Runtime

#### ACTIVATING AUTHORIZATIONS

The operating authorization in the network must be activated in the project properties.

- *navigate to the Network group in Project Properties.*
- *Activate the Authorization in network active property.*
- *Define the Timeout for request [s]:*
  
  Defines the period of time in which a computer can respond to an approval request. The authorization is automatically approved after this time has expired.
  
  **Default:** 60 seconds

- *Define the Timeout for authorization [s]:*
  
  Defines the period of time in which a computer that has authorization must report to the Primary Server. The authorization is automatically approved after this time has expired. Connection interruptions in the network are therefore recognized. The authorization can therefore not be blocked by a compute that cannot be contacted.
  
  **Default:** 60 seconds.

  **Attention:** Select the time period as shorter than the network timeout.
FUNCTIONS FOR AUTHORIZATION IN RUNTIME

To obtain authorizations or to approve these, the corresponding functions must be available in Runtime. To do this, create two buttons that are designated for the corresponding functions:

- Get authorization: Obtains authorization from the user’s own computer
- Approve authorization: Approve authorization or explicit request

GET AUTHORIZATION

1. Create a new function.

2. Select the Authorization in network function in the Network group.

3. The selection dialog for authorizations in the network is opened.

4. Select Get.

If this function is executed in Runtime, the authorization can be obtained from the user’s own station.

APPROVE AUTHORIZATION

1. Create a new function.

2. Select the Authorization in network function in the Network group.

3. The selection dialog for authorizations in the network is opened.

4. Select Approve.
If this function is executed in Runtime, the authorization can be approved again.

**12.2 Authorization in Runtime**

If the **Authorization in network active** property is active, active operations are only executed in Runtime if there is operating authorization for the station.

**EXAMPLE**

If there is no operating authorization, a set value should be written to a variable:

1. The set value is not sent to the hardware.
2. Instead, a message box opens informing you that you do not have the authorization for this project.
3. Click on the button **Obtain the operating authorization**.

**DOES NOT BLOCK AUTHORIZATION FOR ANY OTHER COMPUTER:**

If the operation is freely available:

- You receive the authorization
- You can write the set value
- You can, after the operation, make this available to others using the **Approve authorization** function

**BLOCKS AUTHORIZATION FOR ANOTHER COMPUTER:**

If authorization is blocked:

- A dialog is opened on the computer that is blocking
- The user of the computer that is blocking must explicitly release the authorization
  - **Yes**: The authorization is passed over to the other computer
  - **No**: Authorization remains blocked
• **No reaction**: Countdown corresponding to the time-out time defined in the **Timeout for authorization [s]** property runs out. The authorization is automatically released at 00:00.

### 13. zenon functions in the network

Special zenon functions for the network:

- **Authorization in network** (on page 96)
- **Redundancy switch** (on page 97)

In general, the location of execution (on page 104) must be noted when using functions in the network. For some functions, the location of execution can be freely configured; this is fixed for others.

#### 13.1 Authorization in network

To obtain authorizations or to approve these, the corresponding functions must be available in Runtime. To do this, create two buttons that are designated for the corresponding functions:

- Get authorization: Obtains authorization from the user's own computer
- Approve authorization: Approve authorization or explicit request

**GET AUTHORIZATION**

1. Create a new function.

2. **Select the Authorization in network function** in the **Network group**.
3. The selection dialog for authorizations in the network is opened.

4. Select Get.

If this function is executed in Runtime, the authorization can be obtained from the user’s own station.

**APPROVE AUTHORIZATION**

1. Create a new function.

2. Select the Authorization in network function in the Network group.

3. The selection dialog for authorizations in the network is opened.

4. Select Approve.

If this function is executed in Runtime, the authorization can be approved again.

### 13.2 Redundancy switch

With this function, switching between the Primary Server and Standby Server is possible. The current Primary Server thus becomes the Standby Server and vice versa. The change is permanent until:

- The function is executed again

or
.Runtime files from the Editor are reloaded

When pressing the *Redundancy switching* function, the Primary Server and Standby Server switch their current roles. In doing so, any ongoing timers for downtime or switching delay are ignored and a regrading is carried out immediately. If there is still a regrading active (such as assignments have not yet been concluded), nothing will happen and a warning is entered in the Diagnosis Viewer. This warning documents the unsuccessful execution of the function in the Diagnosis Viewer.

If the evaluated network is active, the flags for the execution of the function (blocked in the Editor) are manipulated so that the execution is always routed to Server 2. This results in dynamic properties in the API (which, for example can be read via VBA) in Runtime being able to have values other than the values shown in the editor.

If the value of the *Redundancy mode* property is non-dominant or evaluated, the *redundancy switching* function is deactivated.

Scenarios of this being used in practice are, for example: Maintenance work on the Primary Server, improved hardware connection to the Standby Server, etc.

**Information**

*This function is not suitable for testing redundancy, as the behavior differs from that of a server failure.*

**TO CONFIGURE THE FUNCTION:**

1. Create a new function.
2. Select, in the Network group, the *Redundancy switching* function.
   (Further adjustments are not necessary.)
3. Link the function to a button.

**Information**

*The redundancy switching function is not available if:*

- The network is activated
- Evaluated or non-dominant was configured as a redundancy mode.
14. Behavior of zenon modules in the network

With network projects, the behavior of individual modules and functions in the network should be noted.

14.1 AML and CEL

ALARMING

The alarming is administered on the Primary Server. The Primary Server answers requests for alarming from the clients. Changes are synchronized between the Primary Server and Standby Server.

CHRONOLOGICAL EVENT LIST

The CEL is administered on the Primary Server. Changes are synchronized between the Primary Server and the Standby Standby Server.

14.2 Historian

Archiving is carried out on the Primary Server.

The Primary Server synchronizes the archive data with the Standby Server and responds to requests from the clients (such as calling up an Extended Trend screen).

14.3 Batch Control

The module Batch Control is fully capable of using a network in terms of Client/Server technology. This means that Batch recipes can be created, duplicated, edited, deleted, etc. on a Client. The whole recipe management remains always on the server. Likewise the whole process control such as start recipe, pause recipe, stop recipe, etc. can be done from the Client. Also mode changes and manual operations such as jump are possible.
For using Batch Control in a network the following is true:

**ALLOCATION**

- The forcing of allocations can be carried out by Server and Client.

**FUNCTIONS**

Functions are always carried out at the Server.

**PHASES**

- Editing phases in the master recipe:
  - Edit mode: Changes are done locally at the Client.
    If during the editing the recipe is saved on another computer in the network, the current configuration is lost. An appropriate message is displayed and the editing dialog is closed. The new data from the server are displayed.
  - Test mode: Changes are done at the Server.

- Control recipe: Changes are done at the Server.

- If a recipe is saved in the network, all Clients using this recipe are updated.

- If a recipe is opened on a client, the current version on the server is always displayed, even if it has not yet been saved there.

- If a recipe is deleted on a computer, a message is displayed on all computers on which the recipe is opened that the recipe has been deleted.

**MODE**

- The mode (automatic, semi-automatic, manual) can be switched by the server and the client.

- Jumps in the recipe and step-by-step progress of a recipe can be done from Server and Client.
RECIPES

- Recipes can be started and controlled by the zenon server and by zenon clients.
- If parameters in a recipe are changed whilst the recipe is saved on a different zenon client, the change to the parameters is refused and not carried out.
- A master recipe can be changed on the zenon client whilst it switches to test mode on the zenon server and is sent to the zenon client. The changes that were last saved are transferred. This means: If the zenon client saves last, the recipe is switched to editing mode again. If the zenon server saves last, the change to the zenon clients is discarded and the recipe is in test mode.
- If a communication error occurs when deleting a recipe or an operation template, the deletion is refused with an error message.

WEB CLIENT

With a standard web client:

- The settings for grid and color can be changed
- No recipes can be created or edited
- The size of the editing area cannot be changed
- In the tool bar, all symbols that are not permitted are deactivated; it is not possible to select the corresponding objects.

Web client PRO is not affected by these restrictions.

14.4 User administration

User administration is administered on the Primary Server. Log-in procedure:

1. The login request is sent to the Primary Server.
2. It answers with the list of authorized users.
3. The client verifies the data.

If changes to user administration are made on a client in Runtime, the complete user list is sent from the client to the Primary Server.
Info

**Active Directory, ADAM, ADLDS users**

If Active Directory, ADAM or ADLDS users are used, all computers (regardless of whether they are the Primary Server, Standby Server or Client) communicate directly with the Active Directory, ADAM or ADLDS server.

This means that all computers must be in the corresponding infrastructure (such as Active Directory domains when Active Directory users are used); it is not sufficient that only the Primary Server is in the Active Directory domains with the corresponding users.

14.5 **Files**

Lists for the files of all modules are created when data is exchanged between the Primary Server and the Standby Server. The Primary Server monitors these lists for changes. Changes that are detected are transferred to the Standby Server.

**Attention**

*The Primary Server does not react to watchdogs that are sent by the Standby Server when lists are created. Note this when stipulating the time for the network timeout.*

With Remote Transport, all files required for the project are transferred to the target system.

In doing so, all files are always transferred to the folder:

- **Standard**

  All files that are in the project's Runtime folder (`\RT\FILES\zenon\system\`). These files determine the appearance and behavior of the project and are transferred as standard:
Behavior of zenon modules in the network

**Info**

Files with the following suffixes are not transferred by default:

- .hot
- .ho
- .re
- .ret

**Optional**

In addition, all files that are embedded into the project must be transferred. They are selected using the Active checkbox of the Remote Transport settings. These files are in the following subfolders of the project directory:

- `\zenon\custom\graphics`: for graphics
- `\zenon\custom\lists`: for language tables
- `\zenon\custom\media`: for all media files
- `\zenon\custom\reports`: for the reports of the Report Generator
- `\zenon\custom\help`: for help files
- `\zenon\custom\additional`: for additional files
- `\zenon\custom\additional`: for Report Viewer files
- `\zenon\custom\drivers`: for drivers
- `\zenon\custom\drivers`: for Report Viewer files
- `\zenon\custom\drivers`: for Report Viewer files
- `\straton`: for straton

**Recommendation:** Project basis path, graphics, language tables, report tables and media files are always transferred.
The following are transferred from the basis path by default: The files `project.ini`, `Projekt.vba`, `Monitor.mon` and the `Projekt` folder.

As a default zenon always uses relative paths and not absolute paths, so that the files can easily be found on the target system.

For the files that can be transferred optionally, the original paths should be used (empty field under target), so that zenon can find them on the target system.
GLOBAL PROJECT

Attention

If the time difference between the server and the client is more than 5 seconds, no more files are synchronized.

14.6 Extended Trend

Extended Trend shows information from archives and online data. This data is saved in the Primary Server and requested by the Primary Server if required (if a trend screen is called up on the client).

14.7 Functions

For functions that are used in the network:

- The place of execution can be freely configured in some cases
- The place of execution is stipulated in some cases

Information

Scripts combine several functions. The place of execution then depends on the settings of the Execute script function. This setting overwrites the settings of the individual functions.

CONFIGURE PLACE OF EXECUTION

For functions where the place of execution can be freely configured, the corresponding parameters are available in the properties of the function.

To define the place of execution:

1. Navigate to the Execution group in the Properties.
2. Select the desired place of execution by checking the checkbox. Multiple selection is possible:
• Current computer: Function will be executed on the current computer.
• Primary Server: Function will be executed on the Primary Server.
• Standby Server: Function will be executed on the Standby Server.
• Client: Function will be executed on all clients.

OVERVIEW OF FUNCTIONS IN THE NETWORK

The following table shows which functions are executed and where they are executed.

Key:

► Adjustable: Behavior can be configured
  +: Yes
  -: No
  O: Default

► If not adjustable, O identifies the place of execution:
  • Active computer
  • Primary Server
  • Standby Server
  • Client

14.8 Message Control

Message Control will be executed on the Primary Server.

The Primary Server synchronizes with the Standby Server.

14.9 Programming interfaces

VBA AND VSTA

Code in VBA or VSTA is always, by default, executed locally on the system on which it is started or where events occur.

The place of execution can however be defined otherwise when this is called up via the function (on page 104).

PCE

The PCE is always executed locally on the system on which it is started.

14.10 Cross reference list

The use of variables in evaluated networks is also taken into account. The property name of the place of usage is stated as the element name. This is either "event variable" or "evaluations".

You can find out further information in the cross-reference list manual.
14.11 Report Generator & Report Viewer

The *.xrs files of the Report Generator and the *.rd1 files of the Report Viewer are synchronized on all systems in the network (Clients, Standby Server, Primary Server).

**EDITOR**

If the file is modified in the zenon Editor, transferred to the Primary Server and reloaded, it is automatically distributed to the other computers in the network.

**RUNTIME**

If the file is amended in Runtime, the changes are only saved on a temporary basis and replaced the next time a reload takes place or when Runtime is restarted.

14.12 Recipes

The execution of recipes is different for standard recipes and the RGM.

**STANDARD RECIPES**

Standard recipes are managed on the Primary Server and on the Standby Server.

If a standard recipe is changed by a user in Runtime, the client requests the full recipe list from the Primary Server. In the event of changes, the recipe list is sent back to the Primary Server.

---

**Information**

*This list is not identical to that of the file rezepturen.cmp*

If a recipe is changed and executed in Runtime on the client, it is executed with the new values. When the standard recipe, you are given the option to save the changes.

**RECIPEGROUP MANAGER**

When the Recipegroup Manager screen is loaded on the client, a list of all recipe names is requested by the Primary Server. As soon as a recipe is selected, it is loaded by the Primary Server.
### 14.13 Scripts

Scripts combine several functions. The place of execution depends on the settings of the `Execute script` function. This setting overwrites the settings of the individual functions.

The execution of scripts in the network is controlled with predefined scripts:

<table>
<thead>
<tr>
<th>Script</th>
<th>Description</th>
<th>Place of execution</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTOSTART</td>
<td>The script is executed automatically when Runtime starts before the start screen is loaded if the project is the Runtime start project. It is not executed when subordinate projects are started.</td>
<td>Network project: Primary Server</td>
</tr>
<tr>
<td>AUTOEND</td>
<td>The script is executed automatically when Runtime is ended if the project is the Runtime start project. It is not executed when subordinate projects are ended.</td>
<td>Network project: Primary Server</td>
</tr>
<tr>
<td>AUTOSTART_CLIENT</td>
<td>The script is executed automatically on a client when Runtime starts before the start screen is loaded if the project is the Runtime start project. It is not executed when subordinate projects are started.</td>
<td>Client</td>
</tr>
<tr>
<td>AUTOEND_CLIENT</td>
<td>The script is executed automatically on a client when Runtime is ended if the project is the Runtime start project. It is not executed when subordinate projects are ended.</td>
<td>Client</td>
</tr>
<tr>
<td>AUTOSTART_SRVPRJ</td>
<td>Script is executed automatically when Runtime is started for any desired project on the Primary Server before the start screen is loaded.</td>
<td>Server</td>
</tr>
<tr>
<td>AUTOSTART_SRVPRJ</td>
<td>Script is automatically executed when Runtime of a desired project is ended on the Primary Server.</td>
<td>Server</td>
</tr>
</tbody>
</table>

### 14.14 Driver - Variables - limit values

In the zenon network, the Primary Server normally communicates with the controller via the driver. Requests from the Client are routed via the Primary Server. This gets the information from the controller and forwards it to the Client. Limit values are monitored by the Primary Server.
DRIVERS

Drivers are executed on the Primary Server and Standby Server.

INTERNAL VARIABLES

For internal variables, it is possible to define whether each individual variable is calculated locally or in the network in zenon.

To do this:

1. Navigate to the Internal Variable node in the properties of internal variables

2. Define the place of execution using the Calculation property:
   a) Local: The internal variable is evaluated and managed locally for network projects, i.e. also on the Standby Server and the Clients. The values are not synchronized with other computers in the network.
   b) Network: With network projects, the internal variable is evaluated and administered on the project's Primary Server. It has the same value on the Primary Server and all Clients.

LIMIT VALUES AND REACTION MATRICES

In principle, limit values and reaction matrices are monitored on the Primary Server (where the AML is also administered).

Furthermore, the following applies for local internal variables:

- Limit values and reaction matrices are monitored locally on all computers (Primary Server, Standby Server and Clients).
- Linked limit values are only executed where the limit value of the local internal variable was breached.
- Limit value breaches of these variables on the Standby Server or Client are not an alarm.
14.15 **Time control**

Time control will be executed on the Primary Server. The function triggered is executed on the systems that were selected for execution of the function in the settings.

14.16 **Allocations**

Allocations are always executed on the Primary Server.

---

⚠️ **Attention**

This is relevant to local internal variables most of all. These are not executed on the Standby Server or on Clients!

---

15. **Network messages from the system driver**

The following system driver variables are available for this subject area:
### Network messages from the system driver

<table>
<thead>
<tr>
<th>Name</th>
<th>Data type</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Current primary server</strong></td>
<td>STRING</td>
<td>Computer name of the server currently handling processes. If the name was acquired from the hosts file, this will be the name used there. For DNS, this is the Fully Qualified Domain Name.</td>
</tr>
<tr>
<td></td>
<td>local</td>
<td></td>
</tr>
<tr>
<td><strong>Current Primary Server</strong></td>
<td>STRING</td>
<td>Computer name of the server which is currently not handling processes. If the name was acquired from the hosts file, this is the name entered there. For DNS, this is the Fully Qualified Domain Name.</td>
</tr>
<tr>
<td></td>
<td>local</td>
<td></td>
</tr>
<tr>
<td><strong>Number of connected Clients</strong></td>
<td>UDINT</td>
<td>Delivers the number of clients currently connected to the server. This number also includes the standby server, if there is one.</td>
</tr>
<tr>
<td><strong>Authorization: not granted</strong></td>
<td>BOOL</td>
<td>Shows whether a requested authorization is denied in the network. The value of this variable is changed only for a short time and then changed back to the initial state.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>0 = operating authorization request accepted</td>
<td></td>
</tr>
<tr>
<td></td>
<td>1 = operating authorization request declined</td>
<td></td>
</tr>
<tr>
<td><strong>Authorization: Present here</strong></td>
<td>BOOL</td>
<td>Shows whether there is operating authorization for the current project on the local computer.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>0 = No</td>
<td></td>
</tr>
<tr>
<td></td>
<td>1 = Yes</td>
<td></td>
</tr>
<tr>
<td><strong>Authorization: Computer that owns it.</strong></td>
<td>STRING</td>
<td>Shows the name of the computer that has the authorization for the currently loaded project.</td>
</tr>
<tr>
<td><strong>Result of evaluation, Server 1</strong></td>
<td>UDINT</td>
<td>In the event of changes to a variable from the evaluation matrix, this value is written to the corresponding system driver variable for Server 1 and Server 2 after calculation of the new result of the evaluation. The values are equal to one another (server &lt;-&gt; standby), so that the current value is always displayed on both sides. However, after the other side has a failure, this value remains for the attendant variable and only updates itself once it reconnects.</td>
</tr>
</tbody>
</table>
### Result of evaluation, Server 2

<table>
<thead>
<tr>
<th>UDINT</th>
</tr>
</thead>
<tbody>
<tr>
<td>In the event of changes to a variable from the evaluation matrix, this value is written to the corresponding system driver variable for Server 1 and Server 2 after calculation of the new result of the evaluation. The values are equal to one another (server &lt;-&gt; standby), so that the current value is always displayed on both sides. However, after the other side has a failure, this value remains for the attendant variable and only updates itself once it reconnects.</td>
</tr>
</tbody>
</table>

### Names of connected clients

<table>
<thead>
<tr>
<th>STRING</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delivers the names of the clients currently connected to the server. The standby server, if there is one, is also included.</td>
</tr>
</tbody>
</table>

### Network timeout [milliseconds]

<table>
<thead>
<tr>
<th>UDINT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Shows the timeout in milliseconds for the zenon network as configured in the project configuration.</td>
</tr>
</tbody>
</table>

### Primary Server <-> Standby Server data synchronization

<table>
<thead>
<tr>
<th>BOOL</th>
</tr>
</thead>
<tbody>
<tr>
<td>A binary variable that takes the value 1 for a short time when the system performs a redundancy switch between server and standby server.</td>
</tr>
</tbody>
</table>

- 0 = No redundancy switch over
- 1 = Redundancy switch over

### §§ Redundanz-Umschaltung

<table>
<thead>
<tr>
<th>BOOL</th>
</tr>
</thead>
<tbody>
<tr>
<td>Indicates that the connection to the process handling server was lost. Depending on the network position of the computer, this means:</td>
</tr>
</tbody>
</table>

- Dominant Server: While it is not yet the process handling server, the value changes to TRUE if the connection to the process handling server is lost. Always FALSE after synchronization.
- Non-dominant Server: Changes to TRUE if the connection to the dominant server, which was the process handling server, is lost. Changes back to FALSE if the Standby Server was promoted to be the Primary Server. EVALUATION: Preferably via a REMA, as the Alarm Management is also swapped and taken over by the SB at that time. The Online Container is also not suitable because the variables are re-initialized during redundancy switching.
- Client: Changes to TRUE if the connection to the process handling server is lost. Changes back to FALSE if the client connects to the SB computer that is now the process handling server |

## Primary server shut down

**BOOL**

Indicates the regular stop of the process handling server. The value changes to TRUE if the process handling server was stopped properly. FALSE if there is a process handling server in the net.

Depending on the network position of the computer, this means:

- **Dominant Server**: While it is not yet the process handling server, the value changes to TRUE if the process handling server has stopped.
- **Non-dominant Server**: Changes to TRUE if the dominant server, which was the process handling server, has stopped. Changes back to FALSE if the StandBy was promoted to be the process handling server.
- **EVALUATION**: Preferably via a REMA, as the Alarm Management is also swapped and taken over by the SB at that time. The Online Container is also not suitable because the variables are re-initialized during redundancy switching.
- **Client**: Changes to TRUE if the dominant server has stopped. Changes back to FALSE if the client connects to the SB computer that is now the process handling server. Is also TRUE while the process handling non-dominant server changes back to be the non-process handling server.

## Standalone/Primary Server/Standby Server/Client

**DINT**

Shows the type of the local computer in the network.

- \(-1 = \text{Standalone}\)
- \(0 = \text{Client}\)
- \(1 = \text{Primary Server}\)
- \(2 = \text{Standby Server}\)

## §§ Server-Standby im Dateiabgleich

**BOOL**

A binary variable that takes on the value 1 if the server and the standby server are synchronizing files after a redundancy switch.

- \(0 = \text{no file sync}\)
- \(1 = \text{file sync active}\)

## Standby Server failure

**BOOL**

Changes to TRUE if the connection to the currently non-process handling server is terminated unexpectedly. If
there is a connection, the value is FALSE.

Depending on the network position of the computer, this means:

- **Dominant Server:** The variable only acts as described from the time when the standby became the server handling the process.
- **Non-dominant Server:** If, during file synchronization, the connection to a server that is dominant but is not handling the process is interrupted, the value changes to TRUE. Always FALSE if not the server handling the process.
- **Client:** As per server handling the process.

<td><strong>BOOL</strong></td>
</tr>
<tr>
<td>TRUE if the non-process handling server has registered at the process-handling server and if the data update was performed and the connection between the two computers is active.</td>
<td></td>
</tr>
</tbody>
</table>

Depending on the network position of the computer, this means:

- **Dominant Server:** Only from the time when the standby became the server handling the process does the variable act as described.
- **Non-dominant Server:** If this is ended during file synchronization with a server that is dominant but is not handling the process, the value changes to TRUE. Always FALSE if not the server handling the process.
- **Client:** As per server handling the process.

**Standby Server started:**

TRUE if the non-process handling server has registered at the process-handling server and if the data update was performed and the connection between the two computers is active.

Depending on the network position of the computer, this means:

- **Dominant Server:** Only from the time when the standby became the server handling the process does the variable act as described.
- **Non-dominant Server:** Becomes TRUE if the dominant server not handling the process starts. Changes to FALSE if the
